Standards Of Fundamental Astronomy Review Board

Release 5

2008 March 1

CONTENTS

1) Introduction

- 2) The SOFA Astronomy Library
- 3) The SOFA Vector/Matrix Library
- 4) The individual routines
- A1 The SOFA copyright notice
- A2 FORTRAN constants
- A3 SOFA Review Board membership

THE IAU-SOFA SOFTWARE LIBRARIES

SOFA stands for "Standards Of Fundamental Astronomy". The SOFA software libraries are a collection of subprograms, in sourcecode form, which implement official IAU algorithms for fundamentalastronomy computations. The subprograms at present comprise 109 "astronomy" routines supported by 52 "vector/matrix" routines, all written in Fortran. In the future the number of astronomy routines will increase, and an implementation in C (and perhaps other languages) will be introduced.

THE SOFA INITIATIVE

SOFA is an IAU Service which operates under Division 1 (Fundamental Astronomy) and reports through Commission 19 (Rotation of the Earth).

The IAU set up the SOFA initiative at the 1994 General Assembly, to promulgate an authoritative set of fundamental-astronomy constants and algorithms. At the subsequent General Assembly, in 1997, the appointment of a SOFA Review Board and the selection of a site for the SOFA Center (the outlet for SOFA products) were announced.

The SOFA initiative was originally proposed by the IAU Working Group on Astronomical Standards (WGAS), under the chairmanship of Toshio Fukushima. The proposal was for "...new arrangements to establish and maintain an accessible and authoritative set of constants, algorithms and procedures that implement standard models used in fundamental astronomy". The SOFA Software Libraries implement the "algorithms" part of the SOFA initiative. They were developed under the supervision of an international panel called the SOFA Review Board. The current membership of this panel is listed in an appendix.

A feature of the original SOFA software proposals was that the products would be self-contained and not depend on other software. This includes basic documentation, which, like the present file, will mostly be plain ASCII text. It should also be noted that there is no assumption that the software will be used on a particular computer and Operating System. Although OS-related facilities may be present (Unix make files for instance, use by the SOFA Center of automatic code management systems, HTML versions of some documentation), the routines themselves will be visible as individual text files and will run on a variety of platforms.

ALGORITHMS

The SOFA Review Board's initial goal has been to create a set of callable subprograms. Whether "subroutines" or "functions", they are all referred to simply as "routines". They are designed for use by software developers wishing to write complete applications; no runnable, free-standing applications are included in SOFA's present plans.

The algorithms are drawn from a variety of sources. Because most of the routines so far developed have either been standard "text-book" operations or implement well-documented standard algorithms, it has not been necessary to invite the whole community to submit algorithms, though consultation with authorities has occurred where necessary. It should also be noted that consistency with the conventions published by the International Earth Rotation Service was a stipulation in the original SOFA proposals, further constraining the software designs. This state of affairs will continue to exist for some time, as there is a large backlog of agreed extensions to work on. However, in the future the Board may decide to call for proposals, and is in the meantime willing to look into any suggestions that are received by the SOFA Center.

SCOPE

The routines currently available are listed in the next two chapters of this document.

The "astronomy" library comprises 109 routines (including one obsolete routine that now appears under a revised name). The areas addressed include calendars, time scales, ephemerides, precession-nutation, star space-motion, and star catalog transformations.

The "vector-matrix" library, comprising 52 routines, contains a collection of simple tools for manipulating the vectors, matrices and angles used by the astronomy routines.

There is no explicit commitment by SOFA to support historical models, though as time goes on a legacy of superseded models will naturally accumulate. There is, for example, no support of B1950/FK4 star coordinates, or pre-1976 precession models, though these capabilities could be added were there significant demand.

Though the SOFA software libraries are rather limited in scope, and are likely to remain so for a considerable time, they do offer distinct advantages to prospective users. In particular, the routines are:

- * authoritative: they are IAU-backed and have been constructed with great care;
- * practical: they are straightforward to use in spite of being precise and rigorous (to some stated degree);
- * accessible and supported: they are downloadable from an easy-tofind place, they are in an integrated and consistent form, they come with adequate internal documentation, and help for users is available.

VERSIONS

Once it has been published, an issue will not be revised or updated and will remain accessible indefinitely. Subsequent issues may, however, include corrected versions under the original filename and routine name. However, where a different model is introduced, it will have a different name.

The issues will be referred to by the date when they were announced. The frequency of re-issue will be decided by the Board, taking into account the importance of the changes and the impact on the user community.

DOCUMENTATION

At present there is little free-standing documentation about individual routines. However, each routine has preamble comments which specify in detail what the routine does and how it is used.

The file sofa_pn.pdf describes the SOFA tools for precession-nutation and other aspects of Earth attitude and includes example code and (see the appendix) diagrams showing the interrelationships between the routines supporting the latest (IAU 2006/2000A) models.

PROGRAMMING STANDARDS

The first releases have been in Fortran 77 only. Work on C counterparts is planned, and related software in other languages is under consideration.

The Fortran code conforms to ANSI X3.9-1978 in all but two minor respects: each has an IMPLICIT NONE declaration, and its name has a prefix of "iau_" and may be longer than 6 characters. A global edit to erase both of these will produce ANSI-compliant code with no change in

its function.

Fortran coding style, and restrictions on the range of language features, have been much debated by the Board, and the results comply with the majority view. There is (at present) no document that defines the standard, but the code itself offers a wide range of examples of what is acceptable.

The routines contain explicit numerical constants (the INCLUDE statement is not part of ANSI Fortran 77). These are drawn from the file consts.lis, which is listed in an appendix.

COPYRIGHT ISSUES

Copyright for all of the SOFA software and documentation is owned by the IAU SOFA Review Board. The Software is made available free of charge for use by private individuals for non-profit research and by non-profit educational, academic and research institutions. Potential commercial users of the Software should contact the Board.

Further details are included in the block of comments which concludes every routine. This block of comments is also given as an appendix to the present document.

ACCURACY

The SOFA policy is to organize the calculations so that the machine accuracy is fully exploited. The gap between the precision of the underlying model or theory and the computational resolution has to be kept as large as possible, hopefully leaving several orders of magnitude of headroom.

The SOFA routines in some cases involve design compromises between rigor and ease of use (and also speed, though nowadays this is seldom a major concern).

ACKNOWLEDGEMENTS

The Board is indebted to a number of contributors, who are acknowledged in the preamble comments of the routines concerned.

The Board's effort is provided by the members' individual institutes.

Resources for operating the SOFA Center are provided by Her Majesty's Nautical Almanac Office, operated by the United Kingdom Hydrographic Office. Support for the contributions of the SOFA Review Board chair is provided by the European Southern Observatory under arrangements with the UK Science and Technology Facilities Council through its astronomy programs at the Rutherford Appleton Laboratory. SOFA Astronomy Library

PREFACE

The routines described here comprise the SOFA astronomy library. Their general appearance and coding style conforms to conventions agreed by the SOFA Review Board, and their functions, names and algorithms have been ratified by the Board. Procedures for soliciting and agreeing additions to the library are still evolving.

At present the routines are all written in Fortran 77, complying with the ANSI standard (X3.9-1978) except in two respects:

- (1) All routine names are prefixed with the string "iau_". If necessary, the string can be removed globally; the result is correctly functioning code.
- (2) All routines include an IMPLICIT NONE statement. This can be removed without affecting the behaviour of the code.

If the "iau_" string and/or the IMPLICIT NONE statements are removed globally, the resulting code is fully ANSI-compliant and is functionally unaffected.

GENERAL PRINCIPLES

The principal function of the SOFA Astronomy Library is to define algorithms. A secondary function is to provide software suitable for convenient direct use by writers of astronomical applications.

The astronomy routines call on the SOFA vector/matrix library routines, which are separately listed.

The routines are designed to exploit the full floating-point accuracy of the machines on which they run, and not to rely on compiler optimizations. Within these constraints, the intention is that the code corresponds to the published formulation (if any).

Dates are always Julian Dates (except in calendar conversion routines) and are expressed as two double precision numbers which sum to the required value.

A distinction is made between routines that implement IAU-approved models and those that use those models to create other results. The former are referred to as "canonical models" in the preamble comments; the latter are described as "support routines".

Using the library requires knowledge of positional astronomy and time-scales. These topics are covered in "Explanatory Supplement to the Astronomical Almanac", P. Kenneth Seidelmann (ed.), University Science Books, 1992. Recent developments are documented in the journals, and references to the relevant papers are given in the SOFA code as required. The IERS Conventions are also an essential reference. The routines concerned with Earth attitude (precession-nutation etc.) are described in the SOFA document sofa_pn.pdf.

ROUTINES

Calendars

CAL2JD	Gregorian calendar to Julian Day number
EPB	Julian Date to Besselian Epoch
EPB2JD	Besselian Epoch to Julian Date
EPJ	Julian Date to Julian Epoch
EPJ2JD	Julian Epoch to Julian Date
JD2CAL	Julian Date to Gregorian year, month, day, fraction

JDCALF Julian Date to Gregorian date for formatted output

Time scales

DAT	Delta(AT)	(=TAI-UTC)	for	а	given	UTC	date
DTDB	TDB-TT						

Earth rotation angle and sidereal time

EEOO	equation of the equinoxes, IAU 2000
EEOOA	equation of the equinoxes, IAU 2000A
EE00B	equation of the equinoxes, IAU 2000B
EE06A	equation of the equinoxes, IAU 2006/2000A
EECT00	equation of the equinoxes complementary terms
EQEQ94	equation of the equinoxes, IAU 1994
ERA00	Earth rotation angle, IAU 2000
GMST00	Greenwich mean sidereal time, IAU 2000
GMST06	Greenwich mean sidereal time, IAU 2006
GMST82	Greenwich mean sidereal time, IAU 1982
GST00A	Greenwich Apparent Sidereal Time, IAU 2000A
GST00B	Greenwich Apparent Sidereal Time, IAU 2000B
GST06	Greenwich apparent ST, IAU 2006, given NPB matrix
GST06A	Greenwich apparent sidereal time, IAU 2006/2000A
GST94	Greenwich Apparent Sidereal Time, IAU 1994

Ephemerides (limited precision)

EPV00	Earth position and velocity
PLAN94	major-planet position and velocity

Precession, nutation, polar motion

BI00 BP00 BP06 BPN2XY C2I00A C2I00B C2I06A C2IXY C2IXY C2IXYS C2T00A C2T00B C2T06A C2TCI0	frame bias components, IAU 2000 frame bias and precession matrices, IAU 2000 frame bias and precession matrices, IAU 2006 extract CIP X,Y coordinates from NPB matrix celestial-to-intermediate matrix, IAU 2000A celestial-to-intermediate matrix, IAU 2000B celestial-to-intermediate matrix, IAU 2006/2000A celestial-to-intermediate matrix, given NPB matrix, IAU 2000 celestial-to-intermediate matrix, given X,Y, IAU 2000 celestial-to-intermediate matrix, given X,Y, IAU 2000 celestial-to-terrestrial matrix, IAU 2000A celestial-to-terrestrial matrix, IAU 2000A celestial-to-terrestrial matrix, IAU 2000A celestial-to-terrestrial matrix, IAU 2000B celestial-to-terrestrial matrix, IAU 2000A

SOFA Vector/Matrix Library

PREFACE

The routines described here comprise the SOFA vector/matrix library. Their general appearance and coding style conforms to conventions agreed by the SOFA Review Board, and their functions, names and algorithms have been ratified by the Board. Procedures for soliciting and agreeing additions to the library are still evolving.

At present the routines are all written in Fortran 77, complying with the ANSI standard (X3.9-1978) except in two respects:

- All routine names are prefixed with the string "iau_". If necessary, the string can be removed globally; the result is correctly functioning code.
- (2) All routines include an IMPLICIT NONE statement. This can be removed without affecting the behaviour of the code.

If the "iau_" string and/or the IMPLICIT NONE statements are removed globally, the resulting code is fully ANSI-compliant and is functionally unaffected.

GENERAL PRINCIPLES

The library consists mostly of routines which operate on ordinary Cartesian vectors (x,y,z) and 3x3 rotation matrices. However, there is also support for vectors which represent velocity as well as position and vectors which represent rotation instead of position. The vectors which represent both position and velocity may be considered still to have dimensions (3), but to comprise elements each of which is two numbers, representing the value itself and the time derivative. Thus:

- * "Position" or "p" vectors (or just plain 3-vectors) have dimension
 (3) in Fortran and [3] in C.
- * "Position/velocity" or "pv" vectors have dimensions (3,2) in Fortran and [2][3] in C.
- * "Rotation" or "r" matrices have dimensions (3,3) in Fortran and [3][3] in C. When used for rotation, they are "orthogonal"; the inverse of such a matrix is equal to the transpose. Most of the routines in this library do not assume that r-matrices are necessarily orthogonal and in fact work on any 3x3 matrix.
- * "Rotation" or "r" vectors have dimensions (3) in Fortran and [3] in C. Such vectors are a combination of the Euler axis and angle and are convertible to and from r-matrices. The direction is the axis of rotation and the magnitude is the angle of rotation, in radians. Because the amount of rotation can be scaled up and down simply by multiplying the vector by a scalar, r-vectors are useful for representing spins about an axis which is fixed.
- * The above rules mean that in terms of memory address, the three velocity components of a pv-vector follow the three position components. Application code is permitted to exploit this and all other knowledge of the internal layouts: that x, y and z appear in that order and are in a right-handed Cartesian coordinate system etc. For example, the cp function (copy a p-vector) can be used to copy the velocity component of a pv-vector (indeed, this is how the CPV routine is coded).
- * The routines provided do not completely fill the range of operations that link all the various vector and matrix options, but are confined to functions that are required by other parts of the SOFA software or which are likely to prove useful.

In addition to the vector/matrix routines, the library contains some routines related to spherical angles, including conversions to and from sexagesimal format.

Using the library requires knowledge of vector/matrix methods, spherical trigonometry, and methods of attitude representation. These topics are covered in many textbooks, including "Spacecraft Attitude Determination and Control", James R. Wertz (ed.), Astrophysics and Space Science Library, Vol. 73, D. Reidel Publishing Company, 1986.

OPERATIONS INVOLVING P-VECTORS AND R-MATRICES

Initialize

ZP	zero p-vector
ZR	initialize r-matrix to null
IR	initialize r-matrix to identity

Copy/extend/extract

CP	сору	p-vector
CR	сору	r-matrix

Build rotations

RX	rotate	r-matrix	about	х
RY	rotate	r-matrix	about	У
RZ	rotate	r-matrix	about	z

Spherical/Cartesian conversions

S2C	spherical to unit vector
C2S	unit vector to spherical
S2P	spherical to p-vector
P2S	p-vector to spherical

Operations on vectors

PPP	p-vector plus p-vector
PMP	p-vector minus p-vector
PPSP	p-vector plus scaled p-vector
PDP	inner (=scalar=dot) product of two p-vectors
PXP	outer (=vector=cross) product of two p-vectors
PM	modulus of p-vector
PN	normalize p-vector returning modulus
SXP	multiply p-vector by scalar

Operations on matrices

RXR	r-matrix multiply
TR	transpose r-matrix

Matrix-vector products

RXP	product o	эf	r-matrix and	f	p-vector		
TRXP	product o	сf	transpose of	E	r-matrix	and	p-vector

Separation and position-angle

SEPP	angular separation from p-vectors
SEPS	angular separation from spherical coordinates
PAP	position-angle from p-vectors
PAS	position-angle from spherical coordinates

Rotation vectors

RV2M	r-vector	to	r-matrix
RM2V	r-matrix	to	r-vector

OPERATIONS INVOLVING PV-VECTORS

Initialize

	B 0 10 0	put troater
ZPV	zero	pv-vector

Copy/extend/extract

CPV	copy pv-vector
P2PV	append zero velocity to p-vector
PV2P	discard velocity component of pv-vector

Spherical/Cartesian conversions

S2PV	spherical	to	pv-vector
PV2S	pv-vector	to	spherical

Operations on vectors

PVPPV	pv-vector plus pv-vector
PVMPV	pv-vector minus pv-vector
PVDPV	inner (=scalar=dot) product of two pv-vectors
PVXPV	outer (=vector=cross) product of two pv-vectors
PVM	modulus of pv-vector
SXPV	multiply pv-vector by scalar
S2XPV	multiply pv-vector by two scalars
PVU	update pv-vector
PVUP	update pv-vector discarding velocity

Matrix-vector products

RXPV	product c	сf	r-matrix and	pv-vector		
TRXPV	product c	сf	transpose of	r-matrix	and	pv-vector

OPERATIONS ON ANGLES

ANP	normalize radians to range 0 to 2pi
ANPM	normalize radians to range -pi to +pi
A2TF	decompose radians into hms
A2AF	decompose radians into d ' "
D2TF	decompose days into hms

SUBROUTINE iau_A2AF (NDP, ANGLE, SIGN, IDMSF) *+ * iau_A2AF * * _ _ _ _ _ * Decompose radians into degrees, arcminutes, arcseconds, fraction. * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. * * Status: vector/matrix support routine. * Given: * NDP i resolution (Note 1) * ANGLE d angle in radians * * Returned: '+' or '-' * SIGN С i(4) * degrees, arcminutes, arcseconds, fraction IDMSF * * Called: * iau_D2TF decompose days to hms * * Notes: * * 1) NDP is interpreted as follows: * NDP resolution * ...0000 00 00 : * -7 1000 00 00 * 100 00 00 -6 * -5 10 00 00 * $^{-4}$ 1 00 00 * -3 0 10 00 * -2 0 01 00 * -1 0 00 10 * 0 0 00 01 * 0 00 00.1 1 * 2 0 00 00.01 * 0 00 00.001 3 0 00 00.000... : * 2) The largest positive useful value for NDP is determined by the size of ANGLE, the format of DOUBLE PRECISION floating-point * * numbers on the target platform, and the risk of overflowing IDMSF(4). On a typical platform, for ANGLE up to 2pi, the available floating-point precision might correspond to NDP=12. * * However, the practical limit is typically NDP=9, set by the * capacity of a 32-bit IDMSF(4). 3) The absolute value of ANGLE may exceed 2pi. In cases where it does not, it is up to the caller to test for and handle the * * case where ANGLE is very nearly 2pi and rounds up to 360 degrees, * by testing for IDMSF(1)=360 and setting IDMSF(1-4) to zero. * *_

SUBROUTINE iau_A2TF (NDP, ANGLE, SIGN, IHMSF) *+ * iau_A2TF * * _ _ _ _ _ * Decompose radians into hours, minutes, seconds, fraction. * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. * * Status: vector/matrix support routine. * Given: * NDP i resolution (Note 1) * ANGLE d angle in radians * * Returned: '+' or '-' * SIGN С i(4) * hours, minutes, seconds, fraction IHMSF * * Called: * iau_D2TF decompose days to hms * * Notes: * * 1) NDP is interpreted as follows: * NDP resolution * ...0000 00 00 : * -7 1000 00 00 * 100 00 00 -6 * 10 00 00 -5 * $^{-4}$ 1 00 00 * -3 0 10 00 * -2 0 01 00 * -1 0 00 10 * 0 0 00 01 * 0 00 00.1 1 * 2 0 00 00.01 * 0 00 00.001 3 0 00 00.000... : * * 2) The largest useful value for NDP is determined by the size of ANGLE, the format of DOUBLE PRECISION floating-point numbers on the target platform, and the risk of overflowing IHMSF(4). On a typical platform, for ANGLE up to 2pi, the available * * floating-point precision might correspond to NDP=12. However, * the practical limit is typically NDP=9, set by the capacity of * a 32-bit IHMSF(4). 3) The absolute value of ANGLE may exceed 2pi. In cases where it does not, it is up to the caller to test for and handle the * * case where ANGLE is very nearly 2pi and rounds up to 24 hours, * by testing for IHMSF(1)=24 and setting IHMSF(1-4) to zero. * *_

DOUBLE PRECISION FUNCTION iau_ANP (A) *+ * _ _ _ * iau_ANP * _ _ _ _ _ _ _ _ _ * * Normalize angle into the range 0 <= A < 2pi. * This routine is part of the International Astronomical Union's SOFA (Standards of Fundamental Astronomy) software collection. * * * * Status: vector/matrix support routine. * * Given: * d angle (radians) Α * * Returned: * iau_ANP d angle in range 0-2pi * *_

DOUBLE PRECISION FUNCTION iau_ANPM (A) *+ * _ _ * iau_ANPM * - - - - - - - - -* * Normalize angle into the range -pi <= A < +pi. * This routine is part of the International Astronomical Union's SOFA (Standards of Fundamental Astronomy) software collection. * * * * Status: vector/matrix support routine. * * Given: * d angle (radians) А * * Returned: * iau_ANPM d angle in range +/-pi * *_

SUBROUTINE iau_BIOO (DPSIBI, DEPSBI, DRA) *+ * iau_BI00 * * * Frame bias components of IAU 2000 precession-nutation models (part of * MHB2000 with additions). * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: canonical model. * Returned: * DPSIBI, DEPSBI d longitude and obliquity corrections Ы the ICRS RA of the J2000 mean equinox DRA * Notes 1) The frame bias corrections in longitude and obliquity (radians) are required in order to correct for the offset between the GCRS * pole and the mean J2000 pole. They define, with respect to the GCRS frame, a J2000 mean pole that is consistent with the rest of the IAU 2000A precession-nutation model. 2) In addition to the displacement of the pole, the complete description of the frame bias requires also an offset in right ascension. This is not part of the IAU 2000A model, and is from Chapront et al. (2002). It is returned in radians. 3) This is a supplemented implementation of one aspect of the IAU 2000A nutation model, formally adopted by the IAU General Assembly in 2000, namely MHB2000 (Mathews et al. 2002). References: Chapront, J., Chapront-Touze, M. & Francou, G., Astron.Astrophys., 387, 700, 2002. * * Mathews, P.M., Herring, T.A., Buffet, B.A., "Modeling of nutation and precession New nutation series for nonrigid Earth and * * insights into the Earth's interior", J.Geophys.Res., 107, B4, * 2002. The MHB2000 code itself was obtained on 9th September 2002 from ftp://maia.usno.navy.mil/conv2000/chapter5/IAU2000A. * *_

SUBROUTINE iau_BP00 (DATE1, DATE2, RB, RP, RBP) *+ * iau_BP00 * * - - - - -* Frame bias and precession, IAU 2000. * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: canonical model. * * Given: * DATE1,DATE2 d TT as a 2-part Julian Date (Note 1) * Returned: d(3,3) frame bias matrix (Note 2) RB precession matrix (Note 3) * RP d(3,3) * RBP d(3,3) bias-precession matrix (Note 4) * * Notes: 1) The TT date DATE1+DATE2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, among others: DATE1 DATE2 2450123.7D0 0D0(JD method) 2451545D0 -1421.3D0 (J2000 method) 50123.2D0 2400000.5D0 (MJD method) 2450123.5D0 0.2D0 (date & time method) * The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the * optimum resolution. The MJD method and the date & time methods * are both good compromises between resolution and convenience. * 2) The matrix RB transforms vectors from GCRS to mean J2000 by * applying frame bias. * 3) The matrix RP transforms vectors from J2000 mean equator and * equinox to mean equator and equinox of date by applying precession. * 4) The matrix RBP transforms vectors from GCRS to mean equator and equinox of date by applying frame bias then precession. It is the * product RP x RB. Called: iau_BI00 frame bias components, IAU 2000 IAU 2000 precession adjustments * iau_PR00 initialize r-matrix to identity iau_IR * rotate around X-axis iau_RX iau_RY rotate around Y-axis rotate around Z-axis iau RZ iau_RXR product of two r-matrices * Reference: Capitaine, N., Chapront, J., Lambert, S. and Wallace, P., "Expressions for the Celestial Intermediate Pole and Celestial Ephemeris Origin consistent with the IAU 2000A precession-nutation model", Astronomy & Astrophysics, 400, 1145-1154 (2003) n.b. The celestial ephemeris origin (CEO) was renamed "celestial intermediate origin" (CIO) by IAU 2006 Resolution 2.

SUBROUTINE iau_C2IXY (DATE1, DATE2, X, Y, RC2I) *+ * iau_C2IXY * * Form the celestial to intermediate-frame-of-date matrix for a given * date when the CIP X,Y coordinates are known. IAU 2000. This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: support routine. * Given: * DATE1,DATE2 TT as a 2-part Julian Date (Note 1) d Celestial Intermediate Pole (Note 2) X,Y d Returned: d(3,3) celestial-to-intermediate matrix (Note 3) RC2I * Notes: 1) The TT date DATE1+DATE2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, among others: DATE1 DATE2 2450123.7D0 0D0(JD method) 2451545D0 -1421.3D0 (J2000 method) 50123.2D0 2400000.5D0 (MJD method) 2450123.5D0 0.2D0 (date & time method) The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience. 2) The Celestial Intermediate Pole coordinates are the x,y components of the unit vector in the Geocentric Celestial Reference System. 3) The matrix RC2I is the first stage in the transformation from celestial to terrestrial coordinates: [TRS] = RPOM * R_3(ERA) * RC2I * [CRS] * = RC2T * [CRS] where [CRS] is a vector in the Geocentric Celestial Reference System and [TRS] is a vector in the International Terrestrial Reference System (see IERS Conventions 2003), ERA is the Earth Rotation Angle and RPOM is the polar motion matrix. * 4) Although its name does not include "00", this routine is in fact specific to the IAU 2000 models. * Called: * iau_C2IXYS celestial-to-intermediate matrix, given X,Y and s the CIO locator s, given X,Y, IAU 2000A iau_S00 * Reference: McCarthy, D. D., Petit, G. (eds.), IERS Conventions (2003), IERS Technical Note No. 32, BKG (2004) * * * *_

```
SUBROUTINE iau_C2IXYS ( X, Y, S, RC2I )
*+
*
   iau_C2IXYS
*
*
*
  Form the celestial to intermediate-frame-of-date matrix given the CIP
*
  X,Y and the CIO locator s.
*
   This routine is part of the International Astronomical Union's
*
   SOFA (Standards of Fundamental Astronomy) software collection.
   Status: support routine.
*
*
   Given:
*
                  d
                           Celestial Intermediate Pole (Note 1)
     Х,Ү
*
      S
                  d
                          the CIO locator s (Note 2)
*
   Returned:
*
                d(3,3) celestial-to-intermediate matrix (Note 3)
      RC2I
*
*
  Notes:
*
   1) The Celestial Intermediate Pole coordinates are the x,y components
      of the unit vector in the Geocentric Celestial Reference System.
   2) The CIO locator s (in radians) positions the Celestial
      Intermediate Origin on the equator of the CIP.
*
   3) The matrix RC2I is the first stage in the transformation from
      celestial to terrestrial coordinates:
          [TRS] = RPOM * R_3(ERA) * RC2I * [CRS]
                 = RC2T * [CRS]
      where [CRS] is a vector in the Geocentric Celestial Reference
      System and [TRS] is a vector in the International Terrestrial Reference System (see IERS Conventions 2003), ERA is the Earth
*
      Rotation Angle and RPOM is the polar motion matrix.
*
   Called:
*
      iau_IR
                   initialize r-matrix to identity
*
      iau RZ
                    rotate around Z-axis
                    rotate around Y-axis
      iau_RY
*
*

SUBROUTINE iau_C2S ( P, THETA, PHI )
*+
*
        _ _
  iau_C2S
*
*
  _ _ _ _ _ _ _ _ _
*
*
  P-vector to spherical coordinates.
*
*
  This routine is part of the International Astronomical Union's
*
  SOFA (Standards of Fundamental Astronomy) software collection.
*
*
  Status: vector/matrix support routine.
*
*
  Given:
*
              d(3)
                       p-vector
     Ρ
*
*
  Returned:
*
                        longitude angle (radians)
     THETA
              d
*
     PHI
                        latitude angle (radians)
              d
*
*
  Notes:
*
*
  1) P can have any magnitude; only its direction is used.
*
*
  2) If P is null, zero THETA and PHI are returned.
*
  3) At either pole, zero THETA is returned.
*
*
*_
```

SUBROUTINE iau_C2T00A (TTA, TTB, UTA, UTB, XP, YP, RC2T) *+ * i a u _ C 2 T 0 0 A * Form the celestial to terrestrial matrix given the date, the UT1 and * the polar motion, using the IAU 2000A nutation model. This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: support routine. * * Given: TTA,TTB * d TT as a 2-part Julian Date (Note 1) UT1 as a 2-part Julian Date (Note 1) UTA,UTB d XP,YP d coordinates of the pole (radians, Note 2) * Returned: RC2T d(3,3) celestial-to-terrestrial matrix (Note 3) * Notes: 1) The TT and UT1 dates TTA+TTB and UTA+UTB are Julian Dates, apportioned in any convenient way between the arguments UTA and UTB. For example, JD(UT1)=2450123.7 could be expressed in any of these ways, among others: * UTA UTB 2450123.7D0 000 (JD method) 2451545D0 -1421.3D0 (J2000 method) 2400000.5D0 50123.2D0 (MJD method) 2450123.5D0 0.2D0 (date & time method) The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is The J2000 and MJD methods are good compromises acceptable. between resolution and convenience. In the case of UTA, UTB, the date & time method is best matched to the Earth rotation angle * algorithm used: maximum accuracy (or, at least, minimum noise) is delivered when the UTA argument is for Ohrs UT1 on the day in question and the UTB argument lies in the range 0 to 1, or vice versa. 2) XP and YP are the "coordinates of the pole", in radians, which position the Celestial Intermediate Pole in the International Terrestrial Reference System (see IERS Conventions 2003). In a geocentric right-handed triad u, v, w, where the w-axis points at * the north geographic pole, the v-axis points towards the origin of longitudes and the u axis completes the system, XP = +u and YP = -V. 3) The matrix RC2T transforms from celestial to terrestrial coordinates: [TRS] = RPOM * R_3(ERA) * RC2I * [CRS] = RC2T * [CRS] where [CRS] is a vector in the Geocentric Celestial Reference System and [TRS] is a vector in the International Terrestrial Reference System (see IERS Conventions 2003), RC2I is the celestial-to-intermediate matrix, ERA is the Earth rotation angle and RPOM is the polar motion matrix. 4) A faster, but slightly less accurate result (about 1 mas), can be * obtained by using instead the iau_C2T00B routine. * Called: iau C2I00A celestial-to-intermediate matrix, IAU 2000A

                             0 = OK
*
                            -1 = bad year
                                            (Note 3: JD not computed)
                            -2 = bad month (JD not computed)
                            -3 = bad day
                                            (JD computed)
*
*
  Notes:
*
*
   1) The algorithm used is valid from -4800 March 1, but this
      implementation rejects dates before -4799 January 1.
   2) The Julian Date is returned in two pieces, in the usual SOFA
*
*
      manner, which is designed to preserve time resolution.
                                                                The
*
      Julian Date is available as a single number by adding DJMO and
*
      DJM.
   3) In early eras the conversion is from the "Proleptic Gregorian
      Calendar"; no account is taken of the date(s) of adoption of
*
*
      the Gregorian Calendar, nor is the \ensuremath{\operatorname{AD/BC}} numbering convention
      observed.

SUBROUTINE iau_D2TF (NDP, DAYS, SIGN, IHMSF) *+ * iau_D2TF * * _ _ _ _ _ * * Decompose days to hours, minutes, seconds, fraction. * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. * * Status: vector/matrix support routine. * Given: * NDP i resolution (Note 1) * DAYS d interval in days * * Returned: '+' or '-' * SIGN С i(4) * hours, minutes, seconds, fraction IHMSF * * Notes: * 1) NDP is interpreted as follows: * NDP resolution * ...0000 00 00 : * -7 1000 00 00 100 00 00 10 00 00 * -6 -5 * * $^{-4}$ 1 00 00 * -3 0 10 00 * 0 01 00 -2 * -1 0 00 10 * 0 0 00 01 * 0 00 00.1 1 * 2 0 00 00.01 * 3 0 00 00.001 * 0 00 00.000... * 2) The largest positive useful value for NDP is determined by the size of DAYS, the format of DOUBLE PRECISION floating-point * * numbers on the target platform, and the risk of overflowing * IHMSF(4). On a typical platform, for DAYS up to 1D0, the available floating-point precision might correspond to NDP=12. * However, the practical limit is typically NDP=9, set by the * capacity of a 32-bit IHMSF(4). * 3) The absolute value of DAYS may exceed 1D0. In cases where it does not, it is up to the caller to test for and handle the * case where DAYS is very nearly 1D0 and rounds up to 24 hours, * by testing for IHMSF(1)=24 and setting IHMSF(1-4) to zero. * *_

SUBROUTINE iau_DAT (IY, IM, ID, FD, DELTAT, J) *+ * iau_DAT * _ _ _ * For a given UTC date, calculate delta(AT) = TAI-UTC. * * :-----: IMPORTANT : * : A new version of this routine must be : produced whenever a new leap second is * : announced. There are five items to change on each such occasion: : : : 1) The parameter NDAT must be : increased by 1. : * : 2) A new line must be added to the set * : of DATA statements that initialize the arrays IDATE and DATS. : : 3) The parameter IYV must be set to : : the current year. : * 4) The "Latest leap second" comment : : below must be set to the new leap : : second date. * : 5) The "This revision" comment, later, : * must be set to the current date. : * : : Change (3) must also be carried out : whenever the routine is re-issued, * even if no leap seconds have been : * : added. * : * : Latest leap second: 2006 January 1 * * This routine is part of the International Astronomical Union's SOFA (Standards of Fundamental Astronomy) software collection. * Status: support routine. * Given: * ΙY i UTC: year (Notes 1 and 2) month (Note 2) ΤМ i * ID i day (Notes 2 and 3) FD fraction of day (Note 4) * d * Returned: DELTAT d TAI minus UTC, seconds * status (Note 5): J i 1 = dubious year (Note 1) 0 = OK -1 = bad year -2 = bad month-3 = bad day (Note 3) -4 = bad fraction (Note 4) * Notes: 1) UTC began at 1960 January 1.0 (JD 2436934.5) and it is improper * to call the routine with an earlier epoch. If this is attempted, * zero is returned together with a warning status. * Because leap seconds cannot, in principle, be predicted in advance, a reliable check for dates beyond the valid range is

impossible. To guard against gross errors, a year five or more after the release year of the present routine (see parameter IYV) * is considered dubious. In this case a warning status is returned * but the result is computed in the normal way. * For both too-early and too-late years, the warning status is J=+1. This is distinct from the error status J=-1, which signifies a * year so early that JD could not be computed. * 2) If the specified date is for a day which ends with a leap second, the UTC-TAI value returned is for the period leading up to the leap second. If the date is for a day which begins as a leap second ends, the UTC-TAI returned is for the period following the leap second. 3) The day number must be in the normal calendar range, for example 1 through 30 for April. The "almanac" convention of allowing * such dates as January 0 and December 32 is not supported in this routine, in order to avoid confusion near leap seconds. 4) The fraction of day is used only for dates before the introduction of leap seconds, the first of which occurred at the end of 1971. It is tested for validity (zero to less than 1 is the valid range) even if not used; if invalid, zero is used and status J=-4 is returned. For many applications, setting FD to zero is acceptable; the resulting error is always less than 3 ms (and occurs only pre-1972). 5) The status value returned in the case where there are multiple errors refers to the first error detected. For example, if the month and day are 13 and 32 respectively, JSTAT=-2 (bad month) * will be returned. 6) In cases where a valid result is not available, zero is returned. * * References: 1) For epochs from 1961 January 1 onwards, the expressions from the file ftp://maia.usno.navy.mil/ser7/tai-utc.dat are used. 2) The 5ms timestep at 1961 January 1 is taken from 2.58.1 (p87) of * the 1992 Explanatory Supplement. * Called: * iau CAL2JD Gregorian calendar to Julian Day number *_

DOUBLE PRECISION FUNCTION iau_DTDB (DATE1, DATE2, : UT, ELONG, U, V) *+ * _ _ _ * iau_DTDB * * An approximation to TDB-TT, the difference between barycentric * dynamical time and terrestrial time, for an observer on the Earth. * The different time scales - proper, coordinate and realized - are * related to each other: TAI <- physically realized * offset <- observed (nominally +32.184s) : TT<- terrestrial time : <- definition of TT rate adjustment (L_G) * TCG <- time scale for GCRS : <- iau_DTDB is an implementation "periodic" terms rate adjustment (L_C) <- function of solar-system ephemeris : * TCB <- time scale for BCRS : rate adjustment (-L_B) <- definition of TDB : TDB <- TCB scaled to track TT • "periodic" terms <- -iau_DTDB is an approximation * : <- terrestrial time TΤ * Adopted values for the various constants can be found in the IERS * Conventions (McCarthy & Petit 2003). * This routine is part of the International Astronomical Union's SOFA (Standards of Fundamental Astronomy) software collection. * * Status: canonical model. * * Given: * DATE1,DATE2 d date, TDB (Notes 1-3) universal time (UT1, fraction of one day) UΤ d * ELONG d longitude (east positive, radians) * IJ d distance from Earth spin axis (km) distance north of equatorial plane (km) V d * * Returned: * d TDB-TT (seconds) iau_DTDB * * Notes: * 1) The date DATE1+DATE2 is a Julian Date, apportioned in any convenient way between the arguments DATE1 and DATE2. For * example, JD(TDB)=2450123.7 could be expressed in any of these * ways, among others: * DATE1 DATE2 2450123.7D0 0D0 (JD method) 2451545D0 -1421.3D0 (J2000 method) 50123.2D0 2400000.5D0 (MJD method) 2450123.5D0 0.2D0 (date & time method) * * The JD method is the most natural and convenient to use in cases * where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the

argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both * good compromises between resolution and convenience. * Although the epoch is, formally, barycentric dynamical time (TDB), the terrestrial dynamical time (TT) can be used with no practical * effect on the accuracy of the prediction. 2) TT can be regarded as a coordinate time that is realized as an offset of 32.184s from International Atomic Time, TAI. TT is a specific linear transformation of geocentric coordinate time TCG, which is the time scale for the Geocentric Celestial Reference System, GCRS. 3) TDB is a coordinate time, and is a specific linear transformation * of barycentric coordinate time TCB, which is the time scale for the Barycentric Celestial Reference System, BCRS. 4) The difference TCG-TCB depends on the masses and positions of the bodies of the solar system and the velocity of the Earth. It is dominated by a rate difference, the residual being of a periodic character. The latter, which is modeled by the present routine, comprises a main (annual) sinusoidal term of amplitude approximately 0.00166 seconds, plus planetary terms up to about 20 microseconds, and lunar and diurnal terms up to 2 microseconds. These effects come from the changing transverse Doppler effect and gravitational red-shift as the observer (on the Earth's surface) experiences variations in speed (with respect to the BCRS) and gravitational potential. 5) TDB can be regarded as the same as TCB but with a rate adjustment to keep it close to TT, which is convenient for many applications. The history of successive attempts to define TDB is set out in Resolution 3 adopted by the IAU General Assembly in 2006, which defines a fixed TDB(TCB) transformation that is consistent with contemporary solar-system ephemerides. Future ephemerides will imply slightly changed transformations between TCG and TCB, which could introduce a linear drift between TDB and TT; however, any such drift is unlikely to exceed 1 nanosecond per century. 6) The geocentric TDB-TT model used in the present routine is that of Fairhead & Bretagnon (1990), in its full form. It was originally supplied by Fairhead (private communications with P.T.Wallace, 1990) as a Fortran subroutine. The present routine contains an adaptation of the Fairhead code. The numerical results are essentially unaffected by the changes, the differences with respect to the Fairhead & Bretagnon original being at the 1D-20 s * level. The topocentric part of the model is from Moyer (1981) and Murray (1983), with fundamental arguments adapted from * Simon et al. 1994. It is an approximation to the expression (v / c) . (r / c), where v is the barycentric velocity of the Earth, r is the geocentric position of the observer and * * c is the speed of light. By supplying zeroes for U and V, the topocentric part of the model can be nullified, and the routine will return the Fairhead & Bretagnon result alone. 7) During the interval 1950-2050, the absolute accuracy is better than +/-3 nanoseconds relative to time ephemerides obtained by direct numerical integrations based on the JPL DE405 solar system ephemeris. 8) It must be stressed that the present routine is merely a model, and that numerical integration of solar-system ephemerides is the definitive method for predicting the relationship between TCG and TCB and hence between TT and TDB. DOUBLE PRECISION FUNCTION iau_EECT00 (DATE1, DATE2) *+ * iau_EECT00 * * Equation of the equinoxes complementary terms, consistent with * IAU 2000 resolutions. * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: canonical model. * * Given: * DATE1,DATE2 d TT as a 2-part Julian Date (Note 1) * Returned: * iau EECT00 d complementary terms (Note 2) Notes: * 1) The TT date DATE1+DATE2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, among others: DATE1 DATE2 2450123.7D0 0D0 (JD method) 2451545D0 -1421.3D0 (J2000 method) 2400000.5D0 50123.2D0 (MJD method) 2450123.5D0 0.2D0 (date & time method) The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience. 2) The "complementary terms" are part of the equation of the equinoxes (EE), classically the difference between apparent and mean Sidereal Time: * GAST = GMST + EE* with: EE = dpsi * cos(eps) where dpsi is the nutation in longitude and eps is the obliquity of date. However, if the rotation of the Earth were constant in an inertial frame the classical formulation would lead to apparent irregularities in the UT1 timescale traceable to side-effects of precession-nutation. In order to eliminate these effects from UT1, "complementary terms" were introduced in 1994 (IAU, 1994) and took effect from 1997 (Capitaine and Gontier, 1993): GAST = GMST + CT + EEBy convention, the complementary terms are included as part of the equation of the equinoxes rather than as part of the mean Sidereal Time. This slightly compromises the "geometrical" interpretation of mean sidereal time but is otherwise inconsequential. The present routine computes CT in the above expression, compatible with IAU 2000 resolutions (Capitaine et al., 2002, and * IERS Conventions 2003). * Called: iau_FAL03 mean anomaly of the Moon

mean anomaly of the Sun mean argument of the latitude of the Moon iau_FALP03 * iau_FAF03 mean argument of the latitude of the Sun iau_FAD03 mean elongation of the Moon's ascending no * * iau_FAOM03 mean longitude of the Moon's ascending node iau_FAVE03 mean longitude of Venus * * * mean longitude of Earth iau_FAE03 * iau_FAPA03 general accumulated precession in longitude * * References: * Capitaine, N. & Gontier, A.-M., Astron. Astrophys., 275, 645-650 (1993) * * * Capitaine, N., Wallace, P.T. and McCarthy, D.D., "Expressions to implement the IAU 2000 definition of UT1", Astronomy & Astrophysics, 406, 1135-1149 (2003) * * * * * IAU Resolution C7, Recommendation 3 (1994) * McCarthy, D. SUBROUTINE iau_EPV00 (DATE1, DATE2, PVH, PVB, JSTAT) *+ * iau_EPV00 * * * Earth position and velocity, heliocentric and barycentric, with * respect to the Barycentric Celestial Reference System. * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: support routine. * * Given: * DATE1 d TDB date part A (Note 1) * DATE2 d TDB date part B (Note 1) * Returned: d(3,2) PVH heliocentric Earth position/velocity (AU,AU/day) PVB d(3,2) barycentric Earth position/velocity (AU,AU/day) * JSTAT status: 0 = OKi +1 = warning: date outside 1900-2100 AD * Notes: 1) The epoch EPOCH1+EPOCH2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TDB)=2450123.7 could be expressed in any of these ways, among others: EPOCH2 EPOCH1 2450123.7D0 0D0 (JD method) 2451545D0 -1421.3D0 (J2000 method) 2400000.5D0 50123.2D0 (MJD method) 2450123.5D0 0.2D0 (date & time method) The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution * is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience. However, the accuracy of the result is more likely to be * limited by the algorithm itself than the way the epoch has been * expressed. * 2) On return, the arrays PVH and PVB contain the following: * PVH(1,1) х * PVH(2,1) heliocentric position, AU У * PVH(3,1) 7. * PVH(1,2) xdot * PVH(2,2) ydot heliocentric velocity, AU/d zdot PVH(3,2) * * $PVB(1,1) \times$ PVB(2,1) barycentric position, AU У * PVB(3,1) z * PVB(1,2) xdot PVB(2,2) ydot PVB(3,2) zdot barycentric velocity, AU/d * PVB(3,2) The vectors are with respect to the Barycentric Celestial Reference System. The time unit is one day in TDB. * * 3) The routine is a SIMPLIFIED SOLUTION from the planetary theory VSOP2000 (X. Moisson, P. Bretagnon, 2001, Celes. Mechanics & Dyn. Astron., 80, 3/4, 205-213) and is an adaptation of original *

* Fortran code supplied by P. Bretagnon (private comm., 2000). * * 4) Comparisons over the time span 1900-2100 with this simplified * solution and the JPL DE405 ephemeris give the following results: * * RMS max * Heliocentric: * position error 3.7 11.2 km * 1.4 5.0 mm/s velocity error * * Barycentric: * position error 4.6 13.4 km * velocity error 1.4 4.9 mm/s * * Comparisons with the JPL DE406 ephemeris show that by 1800 and 2200 the position errors are approximately double their 1900-2100 size. By 1500 and 2500 the deterioration is a factor of 10 and by 1000 and 3000 a factor of 60. The velocity accuracy falls off at about half that rate. * * * * * *_

DOUBLE PRECISION FUNCTION iau_EQEQ94 (DATE1, DATE2) *+ * iau_EQEQ94 * * _ _ * Equation of the equinoxes, IAU 1994 model. * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. * Status: canonical model. * Given: * DATE1,DATE2 d TDB date (Note 1) * * Returned: * iau_EQEQ94 d equation of the equinoxes (Note 2) * * Notes: * * 1) The date DATE1+DATE2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, * JD(TDB)=2450123.7 could be expressed in any of these ways, * among others: DATE1 DATE2 * 2450123.7D0 0D0 (JD method) -1421.3D0 2451545D0 (J2000 method) * 2400000.5D0 50123.2D0 (MJD method) 2450123.5D0 0.2D0 (date & time method) * The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way * the argument is handled internally and will deliver the * optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience. * 2) The result, which is in radians, operates in the following sense: Greenwich apparent ST = GMST + equation of the equinoxes * Called: * iau_NUT80 nutation, IAU 1980 mean obliquity, IAU 1980
normalize angle into range +/- pi iau_OBL80 * iau ANPM * * References: * IAU Resolution C7, Recommendation 3 (1994) * Capitaine, N. & Gontier, A.-M., Astron. Astrophys., 275, * 645-650 (1993) * *_

DOUBLE PRECISION FUNCTION iau_ERA00 (DJ1, DJ2) *+ * * iau_ERA00 * _ _ _ _ _ * Earth rotation angle (IAU 2000 model). * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. * Status: canonical model. * Given: * DJ1,DJ2 d UT1 as a 2-part Julian Date (see note) * * The result is the Earth rotation angle (radians), in the range 0 to * 2pi. * * Notes: * * 1) The UT1 date DJ1+DJ2 is a Julian Date, apportioned in any convenient way between the arguments DJ1 and DJ2. For example, JD(UT1)=2450123.7 could be expressed in any of these ways, among others: DJ1 DJ2 2450123.7D0 0D0 (JD method) 2451545D0 -1421.3D0 (J2000 method) 2400000.5D0 50123.2D0 (MJD method) * 2450123.5D0 0.200 (date & time method) The JD method is the most natural and convenient to use in * cases where the loss of several decimal digits of resolution is acceptable. The J2000 and MJD methods are good compromises between resolution and convenience. The date & time method is best matched to the algorithm used: maximum accuracy (or, at * least, minimum noise) is delivered when the DJ1 argument is for * Ohrs UT1 on the day in question and the DJ2 argument lies in the * range 0 to 1, or vice versa. * 2) The algorithm is adapted from Expression 22 of Capitaine et al. 2000. The time argument has been expressed in days directly, * and, to retain precision, integer contributions have been * eliminated. The same formulation is given in IERS Conventions * (2003), Chap. 5, Eq. 14. * Called: * iau_ANP normalize angle into range 0 to 2pi * References: Capitaine N., Guinot B. and McCarthy D.D, 2000, Astron. * Astrophys., 355, 398-405. * McCarthy, D. *
*
  FK5 to Hipparcos rotation and spin.
*
*
   This routine is part of the International Astronomical Union's
*
   SOFA (Standards of Fundamental Astronomy) software collection.
*
*
   Status: support routine.
*
   Returned:
*
      R5H
               d(3,3)
                        r-matrix: FK5 rotation wrt Hipparcos (Note 2)
                        r-vector: FK5 spin wrt Hipparcos (Note 3)
*
      S5H
               d(3)
*
*
   Notes:
*
*
   1) This routine models the FK5 to Hipparcos transformation as a pure rotation and spin; zonal errors in the FK5 catalogue are
*
*
      not taken into account.
   2) The r-matrix R5H operates in the sense:
*
             P_Hipparcos = R5H x P_FK5
*
*
      where P_FK5 is a p-vector in the FK5 frame, and P_Hipparcos is
*
      the equivalent Hipparcos p-vector.
*
   3) The r-vector S5H represents the time derivative of the FK5 to
      Hipparcos rotation. The units are radians per year (Julian,
*
*
      TDB).

*_
```

SUBROUTINE iau_FK5HZ (R5, D5, DATE1, DATE2, RH, DH) *+ * іаи_ F К 5 Н Z * * * Transform an FK5 (J2000) star position into the system of the * Hipparcos catalogue, assuming zero Hipparcos proper motion. This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: support routine. * * Given: * R5 d FK5 RA (radians), equinox J2000, at date D5 FK5 Dec (radians), equinox J2000, at date d DATE1, DATE2 d TDB date (Notes 1,2) * Returned: * RH d Hipparcos RA (radians) * DH d Hipparcos Dec (radians) * Notes: 1) This routine converts a star position from the FK5 system to the Hipparcos system, in such a way that the Hipparcos proper motion is zero. Because such a star has, in general, a non-zero proper motion in the FK5 system, the routine requires the date at which the position in the FK5 system was determined. 2) The date DATE1+DATE2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TDB)=2450123.7 could be expressed in any of these ways, among others: DATE1 DATE2 2450123.7D0 0D0 (JD method) * 2451545D0 -1421.3D0 (J2000 method) 50123.2D0 * 2400000.5D0 (MJD method) 2450123.5D0 0.200 (date & time method) The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods * are both good compromises between resolution and convenience. 3) The FK5 to Hipparcos transformation is modeled as a pure * rotation and spin; zonal errors in the FK5 catalogue are not taken into account. * 4) It was the intention that Hipparcos should be a close * approximation to an inertial frame, so that distant objects have zero proper motion; such objects have (in general) non-zero proper motion in FK5, and this routine returns those fictitious proper motions. 5) The position returned by this routine is in the FK5 J2000 reference system but at date DATE1+DATE2. 6) See also iau_FK52H, iau_H2FK5, iau_HFK5Z. Called: iau_S2C spherical coordinates to unit vector iau_FK5HIP FK5 to Hipparcos rotation and spin * iau_SXP multiply p-vector by scalar iau_RV2M r-vector to r-matrix iau_TRXP product of transpose of r-matrix and p-vector vector product of two p-vectors iau PXP

      GAMB
                 d
                         F-W angle gamma_bar (radians)
*
      PHIB
                         F-W angle phi_bar (radians)
                 d
      PSI
                 d
                         F-W angle psi (radians)
      EPS
                 d
                         F-W angle epsilon (radians)
*
*
*
  Returned:
               d(3,3) rotation matrix
*
     R
*
*
  Notes:
  1) Naming the following points:
            e = J2000 ecliptic pole,
*
            p = GCRS pole,
            E = ecliptic pole of date,
      and
           P = CIP,
      the four Fukushima-Williams angles are as follows:
         GAMB = gamma = epE
         PHIB = phi = pE
         PSI = psi = pEP
         EPS = epsilon = EP
   2) The matrix representing the combined effects of frame bias,
     precession and nutation is:
         NxPxB = R_1(-EPS).R_3(-PSI).R_1(PHIB).R_3(GAMB)
   3) Three different matrices can be constructed, depending on the
      supplied angles:
*
      o To obtain the nutation x precession x frame bias matrix,
         generate the four precession angles, generate the nutation
         components and add them to the psi_bar and epsilon_A angles,
         and call the present routine.
      o To obtain the precession x frame bias matrix, generate the
         four precession angles and call the present routine.
      o To obtain the frame bias matrix, generate the four precession angles for date J2000.0 and call the present routine.
*
      The nutation-only and precession-only matrices can if necessary
      be obtained by combining these three appropriately.
*

DOUBLE PRECISION FUNCTION iau_GMST06 (UTA, UTB, TTA, TTB) *+ * іаи_ G M S T 0 б * * * Greenwich mean sidereal time (consistent with IAU 2006 precession). * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: canonical model. * * Given: UTA, UTB * d UT1 as a 2-part Julian Date (Notes 1,2) TT as a 2-part Julian Date (Notes 1,2) TTA, TTB * d Returned: * * iau GMST06 d Greenwich mean sidereal time (radians) Notes: * 1) The UT1 and TT dates UTA+UTB and TTA+TTB respectively, are both Julian Dates, apportioned in any convenient way between the argument pairs. For example, JD=2450123.7 could be expressed in any of these ways, among others: Part A Part B 2450123.7D0 0D0 (JD method) 2451545D0 -1421.3D0 (J2000 method) 2400000.5D0 50123.2D0 (MJD method) 2450123.5D0 0.2D0 (date & time method) The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable (in the case of UT; the TT is not at all critical in this respect). The J2000 and MJD methods are good compromises between resolution and convenience. For UT, the date & time method is best matched to the algorithm that is used by the Earth rotation angle routine, called internally: maximum accuracy (or, at least, minimum noise) is delivered when the UTA argument is for * Ohrs UT1 on the day in question and the UTB argument lies in the range 0 to 1, or vice versa. 2) Both UT1 and TT are required, UT1 to predict the Earth rotation and TT to predict the effects of precession. If UT1 is used for both purposes, errors of order 100 microarcseconds result. 3) This GMST is compatible with the IAU 2006 precession and must not be used with other precession models. * 4) The result is returned in the range 0 to 2pi. * Called: * iau_ERA00 Earth rotation angle, IAU 2000 iau_ANP normalize angle into range 0 to 2pi * Reference: * Capitaine, N., Wallace, P.T. & Chapront, J., 2005, Astron.Astrophys. 432, 355 * * *_

DOUBLE PRECISION FUNCTION iau_GMST82 (DJ1, DJ2) *+ * iau_GMST82 * * * Universal Time to Greenwich Mean Sidereal Time (IAU 1982 model). * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: canonical model. * * Given: * DJ1, DJ2 d UT1 Julian Date (see note) * * Returned: * iau_GMST82 d Greenwich mean sidereal time (radians) * * Notes: * * 1) The UT1 epoch DJ1+DJ2 is a Julian Date, apportioned in any convenient way between the arguments DJ1 and DJ2. For example, JD(UT1)=2450123.7 could be expressed in any of these ways, among others: DJ1 DJ2 2450123.7D0 0D0 (JD method) 2451545D0 -1421.3D0 (J2000 method) 2400000.5D0 50123.2D0 (MJD method) * 2450123.5D0 0.200 (date & time method) The JD method is the most natural and convenient to use in * cases where the loss of several decimal digits of resolution is acceptable. The J2000 and MJD methods are good compromises between resolution and convenience. The date & time method is best matched to the algorithm used: maximum accuracy (or, at * least, minimum noise) is delivered when the DJ1 argument is for * Ohrs UT1 on the day in question and the DJ2 argument lies in the * range 0 to 1, or vice versa. * 2) The algorithm is based on the IAU 1982 expression. This is always described as giving the GMST at 0 hours UT1. In fact, it gives the * difference between the GMST and the UT, the steady 4-minutes-per-day * drawing-ahead of ST with respect to UT. When whole days are ignored, the expression happens to equal the GMST at 0 hours UT1 each day. * * 3) In this routine, the entire UT1 (the sum of the two arguments DJ1 and DJ2) is used directly as the argument for the standard formula, the constant term of which is adjusted by 12 hours to take account * of the noon phasing of Julian Date. The UT1 is then added, but * * omitting whole days to conserve accuracy. * 4) The result is returned in the range 0 to 2pi. * Called: * iau_ANP normalize angle into range 0 to 2pi References: Transactions of the International Astronomical Union, * * XVIII B, 67 (1983). * Aoki et al., Astron. Astrophys. 105, 359-361 (1982). * *_

DOUBLE PRECISION FUNCTION iau_GST00A (UTA, UTB, TTA, TTB) *+ * i a u _ G S T 0 0 A * * Greenwich Apparent Sidereal Time (consistent with IAU 2000 * resolutions). * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: canonical model. * Given: * UTA, UTB d UT1 as a 2-part Julian Date (Notes 1,2) d TTA, TTB TT as a 2-part Julian Date (Notes 1,2) * Returned: iau_GST00A d Greenwich apparent sidereal time (radians) * * Notes: 1) The UT1 and TT dates UTA+UTB and TTA+TTB respectively, are both Julian Dates, apportioned in any convenient way between the argument pairs. For example, JD=2450123.7 could be expressed in any of these ways, among others: Part A Part B 2450123.7D0 0D0(JD method) -1421.3D0 (J2000 method) 2451545D0 50123.2D0 2400000.5D0 (MJD method) (date & time method) 2450123.5D0 0.2D0 The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable (in the case of UT; the TT is not at all critical in this respect). The J2000 and MJD methods are good compromises between resolution and convenience. For UT, the date & time method is best matched to the algorithm that is used by the Earth * Rotation Angle routine, called internally: maximum accuracy (or, * at least, minimum noise) is delivered when the UTA argument is for Ohrs UT1 on the day in question and the UTB argument lies in the range 0 to 1, or vice versa. 2) Both UT1 and TT are required, UT1 to predict the Earth rotation and TT to predict the effects of precession-nutation. SUBROUTINE iau_NUMAT ( EPSA, DPSI, DEPS, RMATN )
*+
*
    iau_NUMAT
*
*
            _ _ _ _ _ _
*
   Form the matrix of nutation.
*
*
   This routine is part of the International Astronomical Union's
*
   SOFA (Standards of Fundamental Astronomy) software collection.
*
*
   Status: support routine.
*
   Given:
*
      EPSA
                     d
                              mean obliquity of date (Note 1)
*
                              nutation (Note 2)
      DPSI,DEPS
                     d
*
   Returned:
                   d(3,3) nutation matrix (Note 3)
*
      RMATN
*
*
   Notes:
*
*
   1) The supplied mean obliquity EPSA, must be consistent with the
      precession-nutation models from which DPSI and DEPS were obtained.
*
   2) The caller is responsible for providing the nutation components;
      they are in longitude and obliquity, in radians and are with
respect to the equinox and ecliptic of date.
*
   3) The matrix operates in the sense V(true) = RMATN * V(mean),
*
      where the p-vector V(true) is with respect to the true
      equatorial triad of date and the p-vector V(mean) is with
*
      respect to the mean equatorial triad of date.
   Called:
*
      iau_IR
                   initialize r-matrix to identity
                    rotate around X-axis
rotate around Z-axis

SUBROUTINE iau_NUT00A (DATE1, DATE2, DPSI, DEPS) *+ * iau_NUT00A * Nutation, IAU 2000A model (MHB2000 luni-solar and planetary nutation * with free core nutation omitted). This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: canonical model. * Given: * DATE1,DATE2 d TT as a 2-part Julian Date (Note 1) Returned: DPSI.DEPS d nutation, luni-solar + planetary (Note 2) Notes: * 1) The TT date DATE1+DATE2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, among others DATE1 DATE2 2450123.7D0 0D0 (JD method) -1421.3D0 (J2000 method) 2451545D0 2400000.5D0 50123.2D0 (MJD method) 2450123.5D0 0.2D0 (date & time method) The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience. 2) The nutation components in longitude and obliquity are in radians and with respect to the equinox and ecliptic of date. The obliquity at J2000 is assumed to be the Lieske et al. (1977) value of 84381.448 arcsec. Both the luni-solar and planetary nutations are included. The latter are due to direct planetary nutations and the perturbations of the lunar and terrestrial orbits. 3) The routine computes the MHB2000 nutation series with the associated corrections for planetary nutations. It is an implementation of the nutation part of the IAU 2000A precessionnutation model, formally adopted by the IAU General Assembly in 2000, namely MHB2000 (Mathews et al. 2002), but with the free core nutation (FCN - see Note 4) omitted. 4) The full MHB2000 model also contains contributions to the nutations in longitude and obliquity due to the free-excitation of the free-core-nutation during the period 1979-2000. These FCN terms, which are time-dependent and unpredictable, are NOT included in the present routine and, if required, must be independently computed. With the FCN corrections included, the present routine delivers a pole which is at current epochs accurate to a few hundred microarcseconds. The omission of FCN introduces further errors of about that size. 5) The present routine provides classical nutation. The MHB2000 * algorithm, from which it is adapted, deals also with (i) the offsets between the GCRS and mean poles and (ii) the adjustments in longitude and obliquity due to the changed precession rates. These additional functions, namely frame bias and precession

* adjustments, are supported by the SOFA routines iau BI00 and iau_PR00. * * 6) The MHB2000 algorithm also provides "total" nutations, comprising the arithmetic sum of the frame bias, precession adjustments, * luni-solar nutation and planetary nutation. These total nutations can be used in combination with an existing IAU 1976 precession implementation, such as iau_PMAT76, to deliver GCRS-to-true predictions of sub-mas accuracy at current epochs. However, there * are three shortcomings in the MHB2000 model that must be taken into account if more accurate or definitive results are required (see Wallace 2002): (i) The MHB2000 total nutations are simply arithmetic sums, yet in reality the various components are successive Euler rotations. This slight lack of rigor leads to cross terms that exceed 1 mas after a century. The rigorous procedure is to form the GCRS-to-true rotation matrix by applying the bias, precession and nutation in that order. (ii) Although the precession adjustments are stated to be with respect to Lieske et al. (1977), the MHB2000 model does not specify which set of Euler angles are to be used and how the adjustments are to be applied. The most literal and * straightforward procedure is to adopt the 4-rotation epsilon_0, psi_A, omega_A, xi_A option, and to add DPSIPR to psi_A and DEPSPR to both omega_A and eps_A. (iii) The MHB2000 model predates the determination by Chapront et al. (2002) of a 14.6 mas displacement between the ${\tt J2000}$ mean equinox and the origin of the ICRS frame. It should, however, be noted that neglecting this displacement when calculating star coordinates does not lead to a 14.6 mas change in right ascension, only a small second-order distortion in the pattern of the precession-nutation effect. For these reasons, the SOFA routines do not generate the "total nutations" directly, though they can of course easily be generated by calling iau_BI00, iau_PR00 and the present routine and adding the results. 7) The MHB2000 model contains 41 instances where the same frequency appears multiple times, of which 38 are duplicates and three are * triplicates. To keep the present code close to the original MHB algorithm, this small inefficiency has not been corrected. * Called: mean anomaly of the Moon mean argument of the latitude of the Moon * iau FAL03 iau_FAF03 iau_FAOM03 mean longitude of the Moon's ascending node * iau_FAME03 mean longitude of Mercury mean longitude of Venus iau FAVE03 * iau_FAE03 mean longitude of Earth mean longitude of Mars * iau FAMA03 mean longitude of Jupiter iau FAJU03 * iau_FASA03 mean longitude of Saturn iau_FAUR03 mean longitude of Uranus * iau_FAPA03 general accumulated precession in longitude References: * Chapront, J., Chapront-Touze, M. & Francou, G. 2002, * * Astron.Astrophys. 387, 700 Lieske, J.H., Lederle, T., Fricke, W. & Morando, B. 1977, Astron.Astrophys. 58, 1-16 Mathews, P.M., Herring, T.A., Buffet, B.A. 2002, J.Geophys.Res. 107, B4. SUBROUTINE iau_NUT00B (DATE1, DATE2, DPSI, DEPS) *+ * i a u _ N U T O O B * * - - - - - -* Nutation, IAU 2000B model. * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: canonical model. * * Given: * DATE1,DATE2 d TT as a 2-part Julian Date (Note 1) Returned: * DPSI,DEPS d nutation, luni-solar + planetary (Note 2) * * Notes: * * 1) The TT date DATE1+DATE2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, among others: DATE1 DATE2 2450123.7D0 0D0 (JD method) 2451545D0 -1421.3D0 (J2000 method) 50123.2D0 (MJD method) 2400000.5D0 2450123.5D0 0.200 (date & time method) The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience. 2) The nutation components in longitude and obliquity are in radians * and with respect to the equinox and ecliptic of date. The obliquity at J2000 is assumed to be the Lieske et al. (1977) value of 84381.448 arcsec. (The errors that result from using this routine with the IAU 2006 value of 84381.406 arcsec can be neglected.) The nutation model consists only of luni-solar terms, but includes also a fixed offset which compensates for certain long-period planetary terms (Note 7). 3) This routine is an implementation of the IAU 2000B abridged nutation model formally adopted by the IAU General Assembly in 2000. The routine computes the MHB_2000_SHORT luni-solar nutation series (Luzum 2001), but without the associated corrections for the precession rate adjustments and the offset between the GCRS * and J2000 mean poles. 4) The full IAU 2000A (MHB2000) nutation model contains nearly 1400 terms. The IAU 2000B model (McCarthy & Luzum 2003) contains only 77 terms, plus additional simplifications, yet still delivers * results of 1 mas accuracy at present epochs. This combination of accuracy and size makes the IAU 2000B abridged nutation model suitable for most practical applications. The routine delivers a pole accurate to 1 mas from 1900 to 2100 (usually better than 1 mas, very occasionally just outside 1 mas). The full IAU 2000A model, which is implemented in the routine * iau_NUT00A (q.v.), delivers considerably greater accuracy at current epochs; however, to realize this improved accuracy, corrections for the essentially unpredictable free-core-nutation (FCN) must also be included.

5) The present routine provides classical nutation. The * MHB_2000_SHORT algorithm, from which it is adapted, deals also * with (i) the offsets between the GCRS and mean poles and (ii) the adjustments in longitude and obliquity due to the changed * precession rates. These additional functions, namely frame bias and precession adjustments, are supported by the SOFA routines iau_BI00 and iau_PR00. 6) The MHB_2000_SHORT algorithm also provides "total" nutations, comprising the arithmetic sum of the frame bias, precession adjustments, and nutation (luni-solar + planetary). These total nutations can be used in combination with an existing IAU 1976 precession implementation, such as iau PMAT76, to deliver GCRS-totrue predictions of mas accuracy at current epochs. However, for * symmetry with the iau_NUT00A routine (q.v. for the reasons), the SOFA routines do not generate the "total nutations" directly. Should they be required, they could of course easily be generated by calling iau_BI00, iau_PR00 and the present routine and adding the results. 7) The IAU 2000B model includes "planetary bias" terms that are fixed * in size but compensate for long-period nutations. The amplitudes quoted in McCarthy & Luzum (2003), namely Dpsi = -1.5835 mas and Depsilon = +1.6339 mas, are optimized for the "total nutations" method described in Note 6. The Luzum (2001) values used in this SOFA implementation, namely -0.135 mas and +0.388 mas, are optimized for the "rigorous" method, where frame bias, precession and nutation are applied separately and in that order. During the interval 1995-2050, the SOFA implementation delivers a maximum error of 1.001 mas (not including FCN).    Notes:
*
*
   1) The TT date DATE1+DATE2 is a Julian Date, apportioned in any
      convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways,
*
*
      among others
*
              DATE1
                              DATE2
*
*
           2450123.7D0
                                0D0
                                            (JD method)
            2451545D0
                            -1421.3D0
                                            (J2000 method)
                            50123.2D0
           2400000.5D0
                                            (MJD method)
*
           2450123.5D0
                              0.2D0
                                            (date & time method)
*
      The JD method is the most natural and convenient to use in
      cases where the loss of several decimal digits of resolution
*
      is acceptable. The J2000 method is best matched to the way
      the argument is handled internally and will deliver the
*
      optimum resolution. The MJD method and the date & time methods
*
      are both good compromises between resolution and convenience.
   2) This routine returns the set of equinox based angles for the
*
      Capitaine et al. "P03" precession theory, adopted by the IAU in
*
      2006. The angles are set out in Table 1 of Hilton et al. (2006):
*
       EPS0
               epsilon_0

equatorial precession: -1st 323 Euler angle equatorial precession: 2nd 323 Euler angle * ZETAA zeta A THETAA theta_A * PA p_A general precession gamma_J2000 J2000 RA difference of ecliptic poles phi_J2000 J2000 codeclination of ecliptic pole * GAM phi_J2000 PHT * longitude difference of equator poles, J2000 PSI psi_J2000 The returned values are all radians. * 3) Hilton et al. (2006) Table 1 also contains angles that depend on models distinct from the PO3 precession theory itself, namely the * IAU 2000A frame bias and nutation. The quoted polynomials are * used in other SOFA routines: . iau_XY06 contains the polynomial parts of the X and Y series. * . iau_S06 contains the polynomial part of the s+XY/2 series. . iau_PFW06 implements the series for the Fukushima-Williams angles that are with respect to the GCRS pole (i.e. the variants that include frame bias). * 4) The IAU resolution stipulated that the choice of parameterization was left to the user, and so an IAU compliant precession implementation can be constructed using various combinations of the angles returned by the present routine. 5) The parameterization used by SOFA is the Fukushima-Williams angles referred directly to the GCRS pole. These are the final four arguments returned by the present routine, but are more efficiently calculated by calling the routine iau_PFW06. SOFA also supports the direct computation of the CIP GCRS X,Y by series, available by calling iau_XY06. 6) The agreement between the different parameterizations is at the * 1 microarcsecond level in the present era. 7) When constructing a precession formulation that refers to the GCRS pole rather than the dynamical pole, it may (depending on the choice of angles) be necessary to introduce the frame bias * explicitly. Reference: * Hilton, J. et al., 2006, Celest.Mech.Dyn.Astron. 94, 351 * Called: * iau OBL06 mean obliquity, IAU 2006 *_

It is in the range -pi to +pi. The sense is such that if B is a small distance "east" of point A, * * * the bearing is approximately +pi/2. * * 2) Zero is returned if the two points are coincident. * *_

SUBROUTINE iau_PB06 (DATE1, DATE2, BZETA, BZ, BTHETA) *+ * i a u _ P B 0 6 * This routine forms three Euler angles which implement general * precession from epoch J2000.0, using the IAU 2006 model. Frame * bias (the offset between ICRS and mean J2000.0) is included. * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: support routine. * * Given: DATE1,DATE2 d TT as a 2-part Julian Date (Note 1) * Returned: 1st rotation: radians clockwise around z 3rd rotation: radians clockwise around z BZETA d B7 d * BTHETA d 2nd rotation: radians counterclockwise around y * Notes: 1) The TT date DATE1+DATE2 is a Julian Date, apportioned in any convenient way between the arguments DATE1 and DATE2. For example, JD(TT)=2450123.7 could be expressed in any of these ways, among others: DATE1 DATE2 2450123.7D0 0D0 (JD method) 2451545D0 -1421.3D0 (J2000 method) 2400000.5D0 50123.2D0 (MJD method) 2450123.5D0 0.2D0 (date & time method) The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution * is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the * optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience. 2) The traditional accumulated precession angles zeta_A, z_A, theta_A cannot be obtained in the usual way, namely through polynomial expressions, because of the frame bias. The latter means that two of the angles undergo rapid changes near this date. They are * instead the results of decomposing the precession-bias matrix * obtained by using the Fukushima-Williams method, which does not suffer from the problem. The decomposition returns values which * can be used in the conventional formulation and which include frame bias. * 3) The three angles are returned in the conventional order, which * is not the same as the order of the corresponding Euler rotations. The precession-bias matrix is $R_3(-z) \propto R_2(+theta) \propto R_3(-zeta)$. 4) Should zeta_A, z_A, theta_A angles be required that do not contain frame bias, they are available by calling the SOFA routine iau_P06E. * * Called: * iau_PMAT06 PB matrix, IAU 2006 * iau RZ rotate around Z-axis * *_

SUBROUTINE iau_PDP (A, B, ADB) *+ * - - -* iau_PDP * _ _ _ _ _ _ _ _ _ * * p-vector inner (=scalar=dot) product. * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. * * Status: vector/matrix support routine. * * Given: d(3) first p-vector d(3) second p-vector * A * В * * Returned: * d A.B ADB * *_

SUBROUTINE iau_PFW06 (DATE1, DATE2, GAMB, PHIB, PSIB, EPSA) *+ * iau_PFW06 * * * Precession angles, IAU 2006 (Fukushima-Williams 4-angle formulation). * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: canonical model. * * Given: * DATE1,DATE2 d TT as a 2-part Julian Date (Note 1) * * Returned: * d F-W angle gamma_bar (radians) GAMB * PHIB F-W angle phi_bar (radians) d * F-W angle psi_bar (radians) PSTB d * EPSA d F-W angle epsilon_A (radians) * Notes: 1) The TT date DATE1+DATE2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, * among others DATE1 DATE2 2450123.7D0 0D0 (JD method) -1421.3D0 2451545D0 (J2000 method) 2400000.5D0 50123.2D0 (MJD method) * 2450123.5D0 0.2D0 (date & time method) The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution * is acceptable. The J2000 method is best matched to the way * the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods * are both good compromises between resolution and convenience. 2) Naming the following points: e = J2000 ecliptic pole, p = GCRS pole, E = mean ecliptic pole of date, * and P = mean pole of date, * the four Fukushima-Williams angles are as follows: $GAMB = gamma_bar = epE$ PHIB = phi_bar = pE PSIB = psi_bar = pEP EPSA = epsilon_A = EP 3) The matrix representing the combined effects of frame bias and precession is: $PxB = R_1(-EPSA).R_3(-PSIB).R_1(PHIB).R_3(GAMB)$ * 4) The matrix representing the combined effects of frame bias, precession and nutation is simply: $NxPxB = R_1(-EPSA-dE).R_3(-PSIB-dP).R_1(PHIB).R_3(GAMB)$ where dP and dE are the nutation components with respect to the * ecliptic of date. * Reference:

*
  Approximate heliocentric position and velocity of a nominated major
  planet: Mercury, Venus, EMB, Mars, Jupiter, Saturn, Uranus or
  Neptune (but not the Earth itself).
  Given:
                       TDB date part A (Note 1)
      DATE1
               d
      DATE2
               d
                       TDB date part B (Note 1)
     NP
                       planet (1=Mercury, 2=Venus, 3=EMB ... 8=Neptune)
               i
  Returned:
*
     ΡV
               d(3,2) planet pos,vel (heliocentric, J2000, AU, AU/d)
      ъT
               i
                       status: -1 = illegal NP (outside 1-8)
                                0 = OK
                               +1 = warning: date outside 1000-3000 AD
                               +2 = warning: solution failed to converge
*
  Notes
   1) The date DATE1+DATE2 is in the TDB timescale and is a Julian Date,
      apportioned in any convenient way between the two arguments. For
      example, JD(TDB)=2450123.7 could be expressed in any of these
      ways, among others:
             DATE1
                           DATE2
          2450123.7D0
                                        (JD method)
                            0D0
                          -1421.3D0
50123.2D0
           2451545D0
                                        (J2000 method)
          2400000.500
                                        (MJD method)
          2450123.5D0
                            0.2D0
                                        (date & time method)
     The JD method is the most natural and convenient to use in
      cases where the loss of several decimal digits of resolution
      is acceptable. The J2000 method is best matched to the way
      the argument is handled internally and will deliver the
      optimum resolution. The MJD method and the date & time methods
      are both good compromises between resolution and convenience.
      The limited accuracy of the present algorithm is such that any
      of the methods is satisfactory.
*
   2) If an NP value outside the range 1-8 is supplied, an error
*
      status (J = -1) is returned and the PV vector set to zeroes.
   3) For NP=3 the result is for the Earth-Moon Barycenter. To
      obtain the heliocentric position and velocity of the Earth,
      use instead the SOFA routine iau_EPV00.
   4) On successful return, the array PV contains the following:
         PV(1,1) x
                            heliocentric position, AU
         PV(2,1) y
*
         PV(3,1)
         PV(1,2) xdot
        PV(2,2) ydot
PV(3,2) zdot
                           } heliocentric velocity, AU/d
      The reference frame is equatorial and is with respect to the
*
      mean equator and equinox of epoch J2000.
   5) The algorithm is due to J.L. Simon, P. Bretagnon, J. Chapront,
      M. Chapront-Touze, G. Francou and J. Laskar (Bureau des
```

Longitudes, Paris, France). From comparisons with JPL ephemeris DE102, they quote the following maximum errors over the interval 1800-2050: * * * * L (arcsec) B (arcsec) R (km) * * 4 300 Mercury 1 * 5 800 Venus 1 * б EMB 1 1000 * Mars 17 1 7700 Jupiter * 71 5 76000 * 267000 Saturn 81 13 * 7 712000 Uranus 86 Neptune 11 1 253000 * * Over the interval 1000-3000, they report that the accuracy is no worse than 1.5 times that over 1800-2050. Outside 1000-3000 the * * accuracy declines. * Comparisons of the present routine with the JPL DE200 ephemeris * give the following RMS errors over the interval 1960-2025: * * position (km) velocity (m/s) * Mercury 334 0.437 * 1060 Venus 0.855 * 0.815 2010 EMB * Mars 7690 1.98 * Jupiter 71700 7.70 * 199000 19.4 Saturn Uranus 564000 16.4 * 158000 Neptune 14.4 * * Comparisons against DE200 over the interval 1800-2100 gave the * following maximum absolute differences. (The results using * DE406 were essentially the same.) * L (arcsec) B (arcsec) R (km) Rdot (m/s) * 500 * 7 0.7 Mercurv 1 * 7 1 1100 0.9 Venus * 9 EMB 1 1300 1.0 26 9000 2.5 Mars 1 * Jupiter 78 6 82000 8.2 * Saturn 87 14 263000 24.6 86 7 661000 27.4 Uranus * Neptune 11 2 248000 21.4 * 6) The present SOFA re-implementation of the original Simon et al. * Fortran code differs from the original in the following respects: * The date is supplied in two parts. * The result is returned only in equatorial Cartesian form; * the ecliptic longitude, latitude and radius vector are not returned. * The result is in the J2000 equatorial frame, not ecliptic. * * More is done in-line: there are fewer calls to other routines. * * Different error/warning status values are used. A different Kepler's-equation-solver is used (avoiding use of COMPLEX*16). * * Polynomials in T are nested to minimize rounding errors. * * Explicit double-precision constants are used to avoid mixed-mode expressions. * There are other, cosmetic, changes to comply with SOFA

*	style conventions.
*	
*	None of the above changes affects the result significantly.
*	
*	7) The returned status, J, indicates the most serious condition
*	encountered during execution of the routine. Illegal NP is
*	considered the most serious, overriding failure to converge,
*	which in turn takes precedence over the remote epoch warning.
*	
*	Called:
*	iau_ANP normalize angle into range 0 to 2pi

   Notes:
   1) The TT date DATE1+DATE2 is a Julian Date, apportioned in any
*
      convenient way between the two arguments. For example,
      JD(TT)=2450123.7 could be expressed in any of these ways,
*
      among others:
             DATE1
                             DATE2
          2450123.7D0
                              0D0
                                          (JD method)
                           -1421.3D0
           2451545D0
                                          (J2000 method)
          2400000.5D0
                           50123.2D0
                                          (MJD method)
*
          2450123.5D0
                              0.2D0
                                          (date & time method)
      The JD method is the most natural and convenient to use in
      cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way % f(x) = 0
*
      the argument is handled internally and will deliver the
      optimum resolution. The MJD method and the date & time methods
*
      are both good compromises between resolution and convenience.
   2) The caller is responsible for providing the nutation components; they are in longitude and obliquity, in radians and are with
*
*
      respect to the equinox and ecliptic of date. For high-accuracy
      applications, free core nutation should be included as well as
*
      any other relevant corrections to the position of the CIP.
*
   3) The returned mean obliquity is consistent with the IAU 2000
      precession-nutation models.
   4) The matrix RB transforms vectors from GCRS to J2000 mean equator
      and equinox by applying frame bias.
   5) The matrix RP transforms vectors from J2000 mean equator and
*
*
      equinox to mean equator and equinox of date by applying
      precession.
   6) The matrix RBP transforms vectors from GCRS to mean equator and
      equinox of date by applying frame bias then precession. It is the
      product RP x RB.
*
*
   7) The matrix RN transforms vectors from mean equator and equinox of
*
      date to true equator and equinox of date by applying the nutation
      (luni-solar + planetary).
```

* * * *	8) The matrix RBPN transforms vectors from GCRS to true equator and equinox of date. It is the product RN x RBP, applying frame bias, precession and nutation in that order.

SUBROUTINE iau_POM00 (XP, YP, SP, RPOM) *+ * іаи_РОМОО * * _ _ _ _ _ _ * Form the matrix of polar motion for a given date, IAU 2000. * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. * Status: support routine. * Given: * XP,YP d coordinates of the pole (radians, Note 1) d * the TIO locator s' (radians, Note 2) SP * Returned: * RPOM d(3,3) polar-motion matrix (Note 3) Notes: * 1) XP and YP are the "coordinates of the pole", in radians, which position the Celestial Intermediate Pole in the International Terrestrial Reference System (see IERS Conventions 2003). In a geocentric right-handed triad u,v,w, where the w-axis points at the north geographic pole, the v-axis points towards the origin of longitudes and the u axis completes the system, XP = +u and YP = -v. 2) SP is the TIO locator s', in radians, which positions the Terrestrial Intermediate Origin on the equator. It is obtained from polar motion observations by numerical integration, and so is in essence unpredictable. However, it is dominated by a secular drift of about 47 microarcseconds per century, and so can be taken into account by using s' = -47*t, where t is centuries since J2000. The routine iau_SP00 implements this approximation. 3) The matrix operates in the sense V(TRS) = RPOM * V(CIP), meaning * that it is the final rotation when computing the pointing * direction to a celestial source. * Called: * iau_IR initialize r-matrix to identity rotate around Z-axis iau RZ * iau RY rotate around Y-axis * iau_RX rotate around X-axis * Reference: * McCarthy, D. D., Petit, G. (eds.), IERS Conventions (2003), * IERS Technical Note No. 32, BKG (2004) * *_

SUBROUTINE iau_PR00 (DATE1, DATE2, DPSIPR, DEPSPR) *+ * iau_PR00 * Precession-rate part of the IAU 2000 precession-nutation models * (part of MHB2000). * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: canonical model. * Given: * DATE1,DATE2 d TT as a 2-part Julian Date (Note 1) Returned: DPSIPR, DEPSPR d precession corrections (Notes 2,3) Notes * 1) The TT date DATE1+DATE2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, among others DATE1 DATE2 2450123.7D0 0D0 (JD method) 2451545D0 -1421.3D0 (J2000 method) 2400000.5D0 50123.2D0 (MJD method) 2450123.5D0 0.2D0 (date & time method) The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods are both good compromises between resolution and convenience. 2) The precession adjustments are expressed as "nutation components", corrections in longitude and obliquity with respect to the J2000 equinox and ecliptic. 3) Although the precession adjustments are stated to be with respect to Lieske et al. (1977), the MHB2000 model does not specify which set of Euler angles are to be used and how the adjustments are to be applied. The most literal and straightforward procedure is to adopt the 4-rotation epsilon_0, psi_A, omega_A, xi_A option, and to add DPSIPR to psi_A and DEPSPR to both omega_A and eps_A (Wallace 2002). 4) This is an implementation of one aspect of the IAU 2000A nutation model, formally adopted by the IAU General Assembly in 2000, namely MHB2000 (Mathews et al. 2002). * References Lieske, J.H., Lederle, T., Fricke, W. & Morando, B., "Expressions * for the precession quantities based upon the IAU (1976) System of Astronomical Constants", Astron.Astrophys., 58, 1-16 (1977) Mathews, P.M., Herring, T.A., Buffet, B.A., "Modeling of nutation and precession New nutation series for nonrigid Earth and insights into the Earth's interior", J.Geophys.Res., 107, B4, 2002. The MHB2000 code itself was obtained on 9th September 2002 from ftp://maia.usno.navy.mil/conv2000/chapter5/IAU2000A. * Wallace, P.T., "Software for Implementing the IAU 2000 Resolutions", in IERS Workshop 5.1 (2002)

SUBROUTINE iau_PREC76 (EP01, EP02, EP11, EP12, ZETA, Z, THETA) *+ * iau_PREC76 * _ _ _ _ _ _ * IAU 1976 precession model. * * This routine forms the three Euler angles which implement general precession between two epochs, using the IAU 1976 model (as for * * the FK5 catalog). This routine is part of the International Astronomical Union's SOFA (Standards of Fundamental Astronomy) software collection. Status: canonical model. * Given: * EP01,EP02 d TDB starting epoch (Note 1) TDB ending epoch (Note 1) EP11,EP12 d * * Returned: 1st rotation: radians clockwise around \boldsymbol{z} ZETA d 3rd rotation: radians clockwise around z 7. d 2nd rotation: radians counterclockwise around y * THETA d Notes: 1) The epochs EP01+EP02 and EP11+EP12 are Julian Dates, apportioned in any convenient way between the arguments EPn1 and EPn2. For example, JD(TDB)=2450123.7 could be expressed in any of these ways, among others: EPn2 EPn1 2450123.7D0 0D0 (JD method) 2451545D0 -1421.3D0 (J2000 method) 2400000.5D0 50123.2D0 (MJD method) 2450123.5D0 0.2D0 (date & time method) * The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way the argument is handled internally and will deliver the optimum optimum resolution. The MJD method and the date & time methods * are both good compromises between resolution and convenience. The two epochs may be expressed using different methods, but at the risk of losing some resolution. * 2) The accumulated precession angles zeta, z, theta are expressed through canonical polynomials which are valid only for a limited * time span. In addition, the IAU 1976 precession rate is known to be imperfect. The absolute accuracy of the present formulation is better than 0.1 arcsec from 1960AD to 2040AD, better than 1 arcsec from 1640AD to 2360AD, and remains below 3 arcsec for the whole of the period 500BC to 3000AD. The errors exceed 10 arcsec outside the range 1200BC to 3900AD, exceed 100 arcsec outside 4200BC to 5600AD and exceed 1000 arcsec outside 6800BC to 8200AD. 3) The three angles are returned in the conventional order, which * is not the same as the order of the corresponding Euler rotations. The precession matrix is $R_3(-z) \propto R_2(+theta) \propto R_3(-zeta)$. * Reference: Lieske, J.H., 1979. Astron. Astrophys., 73, 282. * * equations (6) & (7), p283. * *_

SUBROUTINE iau_PV2P (PV, P) *+ * _ _ _ * iau_PV2P * _ _ _ _ _ _ _ _ _ _ * Discard velocity component of a pv-vector. * * * This routine is part of the International Astronomical Union's
 * SOFA (Standards of Fundamental Astronomy) software collection. * * Status: vector/matrix support routine. * * Given: * d(3,2) pv-vector PV * * Returned: d(3) p-vector * Ρ * * Called: * iau_CP copy p-vector * *_

SUBROUTINE iau_PV2S (PV, THETA, PHI, R, TD, PD, RD) *+ * iau_PV2S * * _ _ _ _ _ * Convert position/velocity from Cartesian to spherical coordinates. * * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. * * Status: vector/matrix support routine. * Given: * ΡV d(3,2) pv-vector * * Returned: * THETA d longitude angle (radians) latitude angle (radians) * PHI d radial distance * d R * TD d rate of change of THETA * PD d rate of change of PHI rate of change of R * RD d * * Notes: * 1) If the position part of PV is null, THETA, PHI, TD and PD * * are indeterminate. This is handled by extrapolating the * position through unit time by using the velocity part of * PV. This moves the origin without changing the direction * of the velocity component. If the position and velocity * components of PV are both null, zeroes are returned for all * six results. * 2) If the position is a pole, THETA, TD and PD are indeterminate. In such cases zeroes are returned for THETA, TD and PD. * * * *_

SUBROUTINE iau_PVSTAR (PV, RA, DEC, PMR, PMD, PX, RV, J) *+ * i a u _ P V S T A R * * _ _ _ _ _ * Convert star position+velocity vector to catalog coordinates. * * This routine is part of the International Astronomical Union's SOFA (Standards of Fundamental Astronomy) software collection. Status: support routine. * Given (Note 1): * ΡV d(3,2) pv-vector (AU, AU/day) Returned (Note 2): right ascension (radians) RA d * DEC d declination (radians) PMR d RA proper motion (radians/year) PMD d Dec proper motion (radians/year) * РΧ d parallax (arcsec) RV d radial velocity (km/s, positive = receding) J status: i 0 = OK -1 = superluminal speed (Note 5) -2 = null position vector * Notes: 1) The specified pv-vector is the coordinate direction (and its rate * of change) for the epoch at which the light leaving the star reached the solar-system barycenter. 2) The star data returned by this routine are "observables" for an imaginary observer at the solar-system barycenter. Proper motion and radial velocity are, strictly, in terms of barycentric coordinate time, TCB. For most practical applications, it is permissible to neglect the distinction between TCB and ordinary "proper" time on Earth (TT/TAI). The result will, as a rule, be limited by the intrinsic accuracy of the proper-motion and radial-velocity data; moreover, the supplied pv-vector is likely to be merely an intermediate result (for example generated by the routine iau_STARPV), so that a change of time unit will cancel out overall. In accordance with normal star-catalog conventions, the object's * right ascension and declination are freed from the effects of secular aberration. The frame, which is aligned to the catalog equator and equinox, is Lorentzian and centered on the SSB. * Summarizing, the specified pv-vector is for most stars almost * identical to the result of applying the standard geometrical "space motion" transformation to the catalog data. The differences, which are the subject of the Stumpff paper cited below, are: (i) In stars with significant radial velocity and proper motion, the constantly changing light-time distorts the apparent proper motion. Note that this is a classical, not a relativistic, effect. (ii) The transformation complies with special relativity. 3) Care is needed with units. The star coordinates are in radians and the proper motions in radians per Julian year, but the parallax is in arcseconds; the radial velocity is in $\ensuremath{\text{km/s}}\xspace$, but the pv-vector result is in AU and AU/day. * * 4) The proper motions are the rate of change of the right ascension * and declination at the catalog epoch and are in radians per Julian year. The RA proper motion is in terms of coordinate angle, not

*	true angle, a declinations	and will thus be numerically larger at high	
* * 5) Straight-line motion at constant speed in the inertial fr * assumed. If the speed is greater than or equal to the sp * light, the routine aborts with an error status.			
<pre>* * 6) The inverse transformation is performed by the routine iau_STARPV. *</pre>

*
   iau_SEPP
*
            _ _ _ _ _
   _ _ _ _
*
*
  Angular separation between two p-vectors.
*
*
   This routine is part of the International Astronomical Union's
*
  SOFA (Standards of Fundamental Astronomy) software collection.
*
*
   Status: vector/matrix support routine.
*
*
   Given:
*
     Α
                d(3)
                           first p-vector (not necessarily unit length)
*
                d(3)
                           second p-vector (not necessarily unit length)
      В
*
*
   Returned:
*
                           angular separation (radians, always positive)
     S
                d
*
*
  Notes:
*
*
   1) If either vector is null, a zero result is returned.
*
   2) The angular separation is most simply formulated in terms of
*
      scalar product. However, this gives poor accuracy for angles
near zero and pi. The present algorithm uses both cross product
*
*
      and dot product, to deliver full accuracy whatever the size of
*
      the angle.
*
  Called:

DOUBLE PRECISION FUNCTION iau_SP00 (DATE1, DATE2) *+ * iau_SP00 * * * The TIO locator s', positioning the Terrestrial Intermediate Origin * on the equator of the Celestial Intermediate Pole. * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: canonical model. * * Given: * DATE1,DATE2 d TT as a 2-part Julian Date (Note 1) * Returned: * iau SP00 d the TIO locator s' in radians (Note 2) Notes: * 1) The TT date DATE1+DATE2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, * among others: * DATE1 * DATE2 2450123.7D0 0D0 (JD method) 2451545D0 -1421.3D0 (J2000 method) * 2400000.5D0 50123.2D0 (MJD method) 2450123.5D0 0.2D0 (date & time method) * The JD method is the most natural and convenient to use in cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way * * the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods * are both good compromises between resolution and convenience. 2) The TIO locator $\mathbf{s}^{\,\prime}$ is obtained from polar motion observations by * numerical integration, and so is in essence unpredictable. * However, it is dominated by a secular drift of about 47 microarcseconds per century, which is the approximation * evaluated by the present routine. Reference: * McCarthy, D. D., Petit, G. (eds.), IERS Conventions (2003), IERS Technical Note No. 32, BKG (2004) * * * *_

SUBROUTINE iau_STARPM (RA1, DEC1, PMR1, PMD1, PX1, RV1, : EP1A, EP1B, EP2A, EP2B, RA2, DEC2, PMR2, PMD2, PX2, RV2, J) *+ * _ _ _ _ _ _ _ * iau_STARPM * _ _ _ _ _ . * * Star proper motion: update star catalog data for space motion. * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. Status: support routine. * * Given: * right ascension (radians), before RA1 d * DEC1 declination (radians), before d * PMR1 d RA proper motion (radians/year), before * d PMD1 Dec proper motion (radians/year), before * PX1 d parallax (arcseconds), before * RV1 d radial velocity (km/s, +ve = receding), before "before" epoch, part A (Note 1) "before" epoch, part B (Note 1) "after" epoch, part A (Note 1) EP1A d * EP1B d * EP2A d * "after" epoch, part B (Note 1) EP2B d * * Returned: * d right ascension (radians), after RA2 DEC2 d declination (radians), after * RA proper motion (radians/year), after PMR2 d * PMD2 Dec proper motion (radians/year), after d * PX2 d parallax (arcseconds), after * radial velocity (km/s, +ve = receding), after RV2 d * i J status: -1 = system error (should not occur) * 0 = no warnings or errors * 1 = distance overridden (Note 6) 2 = excessive velocity (Note 7) * 4 = solution didn't converge (Note 8) else = binary logical OR of the above warnings * * Notes: * 1) The starting and ending TDB epochs EP1A+EP1B and EP2A+EP2B are * Julian Dates, apportioned in any convenient way between the two parts (A and B). For example, JD(TDB)=2450123.7 could be expressed in any of these ways, among others: * * * EPnA EPnB * 2450123.7D0 0D0 (JD method) -1421.3D0 * 2451545D0 (J2000 method) 50123.2D0 2400000.5D0 (MJD method) * 2450123.5D0 0.2D0 (date & time method) * The JD method is the most natural and convenient to use in * cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way * the argument is handled internally and will deliver the * optimum resolution. The MJD method and the date & time methods * are both good compromises between resolution and convenience. 2) In accordance with normal star-catalog conventions, the object's right ascension and declination are freed from the effects of * secular aberration. The frame, which is aligned to the catalog * equator and equinox, is Lorentzian and centered on the SSB. * * The proper motions are the rate of change of the right ascension and declination at the catalog epoch and are in radians per TDB Julian year. *

*		The parallax	and radial velocity are in the same frame.		
* * *	3)	and the prope	ed with units. The star coordinates are in radians er motions in radians per Julian year, but the in arcseconds.		
* * * *	4)	angle. If th	r motion is in terms of coordinate angle, not true ne catalog uses arcseconds for both RA and Dec proper RA proper motion will need to be divided by cos(Dec)		
* * *	5)	Straight-line is assumed.	e motion at constant speed, in the inertial frame,		
* * * *	6)	An extremely small (or zero or negative) parallax is interpreted to mean that the object is on the "celestial sphere", the radius of which is an arbitrary (large) value (see the iau_STARPV routine for the value used). When the distance is overridden in this way, the status, initially zero, has 1 added to it.			
* * * *	7)	If the space velocity is a significant fraction of c (see the constant VMAX in the routine iau_STARPV), it is arbitrarily set to zero. When this action occurs, 2 is added to the status.			
* * * *	8)	The relativistic adjustment carried out in the iau_STARPV routine involves an iterative calculation. If the process fails to converge within a set number of iterations, 4 is added to the status.			
* * * * * *	Ca	lled: iau_STARPV iau_PVU iau_PDP iau_PVSTAR	star catalog data to space motion pv-vector update a pv-vector scalar product of two p-vectors space motion pv-vector to star catalog data		

SUBROUTINE iau_STARPV (RA, DEC, PMR, PMD, PX, RV, PV, J) *+ * i a u _ S T A R P V * * Convert star catalog coordinates to position+velocity vector. * * This routine is part of the International Astronomical Union's SOFA (Standards of Fundamental Astronomy) software collection. Status: support routine. * Given (Note 1): * RA d right ascension (radians) DEC d declination (radians) PMR RA proper motion (radians/year) d PMD d Dec proper motion (radians/year) parallax (arcseconds) РΧ d radial velocity (km/s, positive = receding) RV d * Returned (Note 2): ΡV d(3,2) pv-vector (AU, AU/day) J i status: 0 = no warnings 1 = distance overridden (Note 6) 2 = excessive velocity (Note 7) 4 = solution didn't converge (Note 8) else = binary logical OR of the above * Notes: 1) The star data accepted by this routine are "observables" for an imaginary observer at the solar-system barycenter. Proper motion and radial velocity are, strictly, in terms of barycentric coordinate time, TCB. For most practical applications, it is permissible to neglect the distinction between TCB and ordinary "proper" time on Earth (TT/TAI). The result will, as a rule, be limited by the intrinsic accuracy of the proper-motion and radial-* velocity data; moreover, the pv-vector is likely to be merely an * intermediate result, so that a change of time unit would cancel out overall. * * In accordance with normal star-catalog conventions, the object's right ascension and declination are freed from the effects of secular aberration. The frame, which is aligned to the catalog equator and equinox, is Lorentzian and centered on the SSB. * 2) The resulting position and velocity pv-vector is with respect to * the same frame and, like the catalog coordinates, is freed from the effects of secular aberration. Should the "coordinate * direction", where the object was located at the catalog epoch, be required, it may be obtained by calculating the magnitude of the position vector PV(1-3,1) dividing by the speed of light in AU/day to give the light-time, and then multiplying the space velocity PV(1-3,2) by this light-time and adding the result to PV(1-3,1). * * Summarizing, the pv-vector returned is for most stars almost identical to the result of applying the standard geometrical "space motion" transformation. The differences, which are the * subject of the Stumpff paper referenced below, are: * (i) In stars with significant radial velocity and proper motion, the constantly changing light-time distorts the apparent proper motion. Note that this is a classical, not a relativistic, effect. (ii) The transformation complies with special relativity. * * 3) Care is needed with units. The star coordinates are in radians * and the proper motions in radians per Julian year, but the parallax is in arcseconds; the radial velocity is in km/s, but

```
*
      the pv-vector result is in AU and AU/day.
*
   4) The RA proper motion is in terms of coordinate angle, not true
      angle. If the catalog uses arcseconds for both RA and Dec proper
*
      motions, the RA proper motion will need to be divided by cos(Dec)
*
      before use.
   5) Straight-line motion at constant speed, in the inertial frame,
*
      is assumed.
*
   6) An extremely small (or zero or negative) parallax is interpreted
      to mean that the object is on the "celestial sphere", the radius
      of which is an arbitrary (large) value (see the constant PXMIN).
      When the distance is overridden in this way, the status, initially
      zero, has 1 added to it.
   7) If the space velocity is a significant fraction of c (see the
      constant VMAX), it is arbitrarily set to zero. When this action
      occurs, 2 is added to the status.
   8) The relativistic adjustment involves an iterative calculation.
      If the process fails to converge within a set number (IMAX) of
      iterations, 4 is added to the status.
   9) The inverse transformation is performed by the routine iau_PVSTAR.

The MJD method and the date & time methods * are both good compromises between resolution and convenience. * * 2) The Celestial Intermediate Pole coordinates are the x,y components of the unit vector in the Geocentric Celestial Reference System. * 3) The CIO locator s (in radians) positions the Celestial Intermediate Origin on the equator of the CIP. * 4) The present routine is faster, but slightly less accurate (about 1 mas in X,Y), than the iau_XYSOOA routine. * Called: classical NPB matrix, IAU 2000B iau PNM00B iau_BPN2XY extract CIP X,Y coordinates from NPB matrix iau_S00 the CIO locator s, given X,Y, IAU 2000A * * Reference: McCarthy, D. D., Petit, G. (eds.), IERS Conventions (2003), * IERS Technical Note No. 32, BKG (2004) * *_

SUBROUTINE iau_XYS06A (DATE1, DATE2, X, Y, S) *+ * i a u _ X Y S O 6 A * * * For a given TT date, compute the X,Y coordinates of the Celestial * Intermediate Pole and the CIO locator s, using the IAU 2006 * precession and IAU 2000A nutation models. * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. * Status: support routine. * * Given: * DATE1,DATE2 d TT as a 2-part Julian Date (Note 1) * Returned: * d Celestial Intermediate Pole (Note 2) Х,Ү * S d the CIO locator s (Note 2) * Notes: 1) The TT date DATE1+DATE2 is a Julian Date, apportioned in any convenient way between the two arguments. For example, JD(TT)=2450123.7 could be expressed in any of these ways, * among others: DATE1 DATE2 2450123.7D0 000 (JD method) 2451545D0 -1421.3D0 (J2000 method) 2400000.5D0 50123.2D0 (MJD method) * 2450123.5D0 0.2D0 (date & time method) The JD method is the most natural and convenient to use in * cases where the loss of several decimal digits of resolution is acceptable. The J2000 method is best matched to the way * the argument is handled internally and will deliver the optimum resolution. The MJD method and the date & time methods * are both good compromises between resolution and convenience. * * 2) The Celestial Intermediate Pole coordinates are the x,y components of the unit vector in the Geocentric Celestial Reference System. * 3) The CIO locator s (in radians) positions the Celestial Intermediate Origin on the equator of the CIP. * 4) Series-based solutions for generating X and Y are also available: see Capitaine & Wallace (2006) and iau_XY06. * Called: classical NPB matrix, IAU 2006/2000A iau PNM06A iau_BPN2XY extract CIP X,Y coordinates from NPB matrix iau_S06 the CIO locator s, given X,Y, IAU 2006 * * References: Capitaine, N. & Wallace, P.T., 2006, Astron.Astrophys. 450, 855 * * Wallace, P.T. & Capitaine, N., 2006, Astron.Astrophys. 459, 981 * *_

SUBROUTINE iau_ZP (P) *+ * - - - - - iau_ZP _____ * * * * Zero a p-vector. * * This routine is part of the International Astronomical Union's
 * SOFA (Standards of Fundamental Astronomy) software collection. * * Status: vector/matrix support routine. * * Returned: * d(3) p-vector Ρ * *_

SUBROUTINE iau_ZPV (PV) *+ * _ _ _ _ _ _ _ i a u _ Z P V * * * * Zero a pv-vector. * * This routine is part of the International Astronomical Union's * SOFA (Standards of Fundamental Astronomy) software collection. * * Status: vector/matrix support routine. * * Returned: * d(3,2) pv-vector PV * * Called: * iau_ZP zero p-vector * *_

```
SUBROUTINE iau_ZR ( R )
*+
*
          - - -
*
   iau_ZR
*
   _ _ _ _ _ _ _ _
*
*
  Initialize an r-matrix to the null matrix.
*

    * This routine is part of the International Astronomical Union's
    * SOFA (Standards of Fundamental Astronomy) software collection.

*
*
   Status: vector/matrix support routine.
*
* Returned:
*
                d(3,3) r-matrix
      R
*
*_
```

IAU STANDARDS OF FUNDAMENTAL ASTRONOMY REVIEW BOARD

Current Membership

John Bangert	United States Naval Observatory
Mark Calabretta	Australia Telescope National Facility
Anne-Marie Gontier	Paris Observatory
Catherine Hohenkerk	Her Majesty's Nautical Almanac Office
Wen-Jing Jin	Shanghai Observatory
Brian Luzum	United States Naval Observatory
Zinovy Malkin	Pulkovo Observatory, St Petersburg
Jeffrey Percival	University of Wisconsin
Patrick Wallace	Rutherford Appleton Laboratory (chair)

Past Members

Wim Brouw	University of	Groningen
Dennis McCarthy	United States	Naval Observatory
George Kaplan	United States	Naval Observatory
Skip Newhall	Jet Propulsion	n Laboratory

The e-mail address for the Board chair is P.T.Wallace@rl.ac.uk
